(Z. Naturforsch. 31a, 1731-1732 [1976]; received October 10, 1976)

For an ionic melt consisting of two components and three ion constituents, we derive the interrelation between the Soret coefficient and the initial and final values of the thermoelectric power of a thermocell containing the melt considered. We only use the general formulas of Thermodynamics of Irreversible Processes and there is no restriction with respect to the valency types of the electrolytes.

For a solution of a single electrolyte in a neutral solvent, the interrelation between the Soret coefficient and the thermoelectric power of a thermocell has been established long ago. For a molten binary mixture, however, such a relation has not yet been derived except in the special case of uni-univalent electrolytes. We will, therefore, develop the general formula for two-component ionic melts with three ion constituents.

The melt consisting of the two components 1 and 2 contains the following ion constituents: α (occurring in component 1 only), β (occurring in component 2 only), and γ (common to both components). For transport quantities such as the heats of transport and the transported entropies and the reference substance is the ion constituent γ.

The state of the melt is described by the thermodynamic temperature T, the pressure P, and the mole fraction x of component 2. The Faraday constant is denoted by F. The chemical potentials of the two components are denoted by μ₁ and μ₂, those of the three ion constituents by μ₂, μβ, and μγ. The symbol (grad μ)T,P refers to that part of the gradient of the chemical potential of substance i which is due to a gradient of x for uniform values of T and P.

Let us consider a melt in which there are gradients of temperature and composition, the pressure being uniform. Then both thermal diffusion (Soret effect) and (ordinary) diffusion (interdiffusion) occur. Eventually a stationary (non-equilibrium) state or steady state will be established where the transport of matter is zero. The general equations governing this steady state in our case (steady Soret effect in ionic melts with three ion constituents) can be shown to be:

\[ z_a F \text{ grad } \psi + (\text{grad } \mu_a)_{T,P} + (\ast Q_a/T) \text{ grad } T = 0, \]  
\[ z_\beta F \text{ grad } \psi + (\text{grad } \mu_\beta)_{T,P} + (\ast Q_\beta/T) \text{ grad } T = 0 \]

where \( z_i \) is the charge number of the ion constituent i (positive or negative for cation or anion constituents, respectively) and \( \psi \) is the (inner) electric potential.

We have the relations:

\[ z_a v_a + z_\gamma v_\gamma = 0, \quad z_\beta v_\beta + z_\gamma v_\gamma' = 0, \]  
\[ \mu_1 = v_a \mu_a + v_\gamma \mu_\gamma, \quad \mu_\beta = v_\beta \mu_\beta + v_\gamma \mu_\gamma', \]  
\[ (1-x) (\text{grad } \mu_1)_{T,P} + x (\text{grad } \mu_2)_{T,P} = 0. \]

Here \( v_i \) denotes the dissociation number of the ion constituent i, the two values for \( \gamma \) (\( v_\gamma \) and \( v_\gamma' \)) relating to the two components 1 and 2, respectively. Combining Eqs. (3) and (4), we find:

\[ \mu_a/z_a - \mu_\beta/z_\beta = \mu_1/(z_a v_a) - \mu_2/(z_\beta v_\beta). \]

We obtain from (5) and (6):

\[ (1/z_a) (\text{grad } \mu_a)_{T,P} - (1/z_\beta) (\text{grad } \mu_\beta)_{T,P} = -[\zeta/(1-x)] (\text{grad } \mu_2)_{T,P} \]

with [see Eq. (3)]

\[ \zeta = z_a v_a (1-x) + z_\beta v_\beta x \]

For \( v_\gamma' = v_\gamma \) the dimensionless quantity \( \zeta \) becomes

\[ \zeta = -1/(z_\gamma v_\gamma) \]

which for \( z_\gamma = \pm 1, v_\gamma = 1 \) reduces to

\[ \zeta = \mp 1. \]

The last relation implies that the two electrolytes (components 1 and 2) are uni-univalent (example: the molten salt mixture KNO₃ + AgNO₃ where \( \zeta = 1 \)).

Dividing Eqs. (1) and (2) by \( z_a \) and \( z_\beta \), respectively, subtracting the resulting equations, and taking account of (7), we find:

\[ \zeta \mu_{22} \text{ grad } x = (\ast Q/T) (1-x) \text{ grad } T \quad \text{(steady state)} \]

where the relation

\[ (\text{grad } \mu_2)_{T,P} = (\text{grad } \mu_2/\text{grad } x)_{T,P} \text{ grad } x \]

and the abbreviations

\[ \mu_{22} = (\text{grad } \mu_2/\text{grad } x)_{T,P} \]  
\[ \ast Q = \ast Q_a/z_a - \ast Q_\beta/z_\beta \]
have been used. Obviously $^*Q$ is a linear combination of the two heats of transport.

We introduce the Soret coefficient $\alpha$ by

$$\text{grad} \, x = \alpha \text{grad} \, T \, x \, \frac{\zeta}{\mu_{22}}. \quad (15)$$

This definition is analogous to that used for binary nonelectrolyte solutions and for solutions of a single electrolyte in a neutral solvent.

It follows from (11) and (15) that

$$^*Q = \alpha \, T \, x \, \frac{\zeta}{\mu_{22}}. \quad (16)$$

Thus the quantity $^*Q$ can be derived from measured values of $\alpha$.

The transported entropies $^*S_\alpha$ and $^*S_\beta$ and the heats of transport $^*Q_\alpha$ and $^*Q_\beta$ of the ion constituents $\alpha$ and $\beta$ are interrelated by

$$^*S_\alpha = \frac{^*Q_\alpha}{T} + S_\alpha, \quad ^*S_\beta = \frac{^*Q_\beta}{T} + S_\beta \quad (17)$$

where $S_\alpha$ and $S_\beta$ are the partial molar entropies of the ion constituents $\alpha$ and $\beta$. The partial molar entropies $S_1$ and $S_2$ of the components 1 and 2 are given by relations analogous to the Equations (4).

We thus derive in view of (3):

$$\frac{S_1}{z_1} - \frac{S_2}{z_2} = \frac{S_1}{(z_1, r_1)} - \frac{S_2}{(z_2, r_2)}, \quad (18)$$

an equation corresponding to (6). Combining (14), (17), and (18), we obtain:

$$^*S_\alpha/z_\alpha - ^*S_\beta/z_\beta = {^*Q}/T + S_1/(z_1, r_1) - S_2/(z_2, r_2), \quad (19)$$

another useful relation.

We now consider a thermocell containing the melt and two chemically identical electrodes reversible to the ion constituent $\beta$ (e.g., two silver electrodes dipping into the molten salt mixture KNO$_3$ + AgNO$_3$). Then the expression for the difference between the final (steady-state) value $\varepsilon_\infty$ and the initial value $\varepsilon_0$ of the thermoelectric power of the thermocell can be shown to be

$$F(\varepsilon_\infty - \varepsilon_0) = t_\alpha \frac{^*Q}{T} = (1 - t_\beta) \frac{^*Q}{T} \quad (20)$$

where Eq. (19) has been used and $t_\alpha$ or $t_\beta$ denotes the (internal) transport number of the ion constituent $\alpha$ or $\beta$, respectively, the ion constituent $\gamma$ being again the reference substance.

We derive our final formula from (16) and (20):

$$F(\varepsilon_\infty - \varepsilon_0) = \alpha \, t_\alpha \, \frac{\zeta}{x} \, \mu_{22} = \sigma \, (1 - t_\beta) \, \frac{\zeta}{x} \, \mu_{22}. \quad (21)$$

Thus there is a general relation among the three measurable quantities $\sigma$, $\varepsilon_0$, and $\varepsilon_\infty$ referring to nonisothermal transport processes. The quantity $\zeta$ may be replaced by $(1 - x)/(z_\beta \, r_\beta \, X_1)$ where $X_1$ denotes the equivalent fraction of component 1.

Since $\mu_{22} > 0$ (stability condition) and $\zeta > 0$ for $z_\beta > 0$ or $\zeta < 0$ for $z_\beta > 0$ [see Eq. (8)], it follows from (21) that $\varepsilon_\infty - \varepsilon_0$ and $\sigma$ have the same sign if $\gamma$ is an anion constituent while $\varepsilon_\infty - \varepsilon_0$ and $\sigma$ have opposite signs if $\gamma$ is a cation constituent.

For $r_\gamma = r_\gamma$, Eq. (21), when combined with (3) and (9), reduces to the relation

$$F(\varepsilon_\infty - \varepsilon_0) = \sigma \, [(1 - t_\gamma)/(z_\beta \, r_\beta)] \, x \, \mu_{22}. \quad (22)$$

We may compare Eq. (22) to the corresponding formula valid for a solution of a single electrolyte (with two ion constituents) in a neutral solvent:

$$F(\varepsilon_\infty - \varepsilon_0) = \sigma \, [(1 - t_\gamma)/(z_\gamma \, r_\gamma, m)] \, m \, (\zeta \mu_{22} \, \varrho m)_{T, P}. \quad (23)$$

Here $t_\gamma$, $z_\gamma$, and $r_\gamma$ are the (Hittorf) transport number, the charge number, and the dissociation number of that ion constituent ($\gamma$) for which the electrodes are reversible and $m$ and $\mu_{22}$ denote the molality and the chemical potential of the electrolyte.

For any binary ionic melt with three ion constituents, the transported entropies $^*S_\alpha$ and $^*S_\beta$ can be derived from measurements of either $\varepsilon_0$ and $\varepsilon_\infty$ or $\varepsilon_0$ and $\sigma$ or $\varepsilon_\infty$ and $\sigma$. This follows from Eqs. (16) and (19) and from relations given earlier. So in this respect, too, the two-component melts resemble electrolyte solutions.

---

3. Though the general equations given by Schönert and Sinistri implicitly contain the desired formula, we will give a new derivation since we do not want to change the reference system, as do the authors mentioned.
6. The question of whether $\alpha$ or $\beta$ is taken to be the "reversible" $r$ is only a matter of choice of the components. The case, however, where the electrodes are reversible to the common ion constituent $\gamma$ ($r=\gamma$) is really different. Here we find that $t_\gamma$ in (20) and (21) has to be replaced by $t_\gamma - X_1$. The formula for the thermoelectric power $\varepsilon$ at any instant (for any value of the mole fraction difference $\Delta x$ corresponding to the temperature difference $\Delta T$ in the melt) results from (21), or from the equation replacing it for $r=\gamma$, if one substitutes $\varepsilon$ for $\varepsilon_\infty$ and $\lim \Delta x/\Delta T$ for $\sigma$ ($1 - x$).
