Notable changes in the molecular conformations of 4-chlorobenzyl alcohol around the C(H\textsubscript{2})-C\textsubscript{ar} and O-C(H\textsubscript{2}) bonds were found to take place at the first-order phase transition point ($T_{c1} = 236$ K). Quite similar phenomena were observed at $T_{c1}$ (217 K) of the isomorphic 4-bromo compound. The two kinds of conformational changes are considered to couple and cause the reversal of the direction of the linear O-H…O hydrogen bond as the compound undergoes the first-order transition. The CH\textsubscript{2}OH moiety participates in several short intermolecular contacts, and a C-H…π interaction exists between the CH\textsubscript{2} and the neighboring phenyl group. These intermolecular factors seem to contribute to the regulation of the molecular conformation in the crystal. The C-O bond length of each compound shortens considerably at $T > T_{c1}$.
