The spin Hamiltonian parameters $g_\parallel$ and $g_\perp$ and the hyperfine structure constants $A_\parallel$ and $A_\perp$ of a tetragonal VO$^{2+}$ center in (NH$_4$)$_2$SbCl$_5$ are investigated, using the perturbation formulas for a 3d$^1$ ion in tetragonally compressed octahedra. In these formulas, the contributions to the spin Hamiltonian parameters from the s- and p-orbitals as well as the spin-orbit coupling coefficient of the Cl$^-$ ligand are taken into account, based on the cluster approach. According to these studies, compression of the ligand octahedra results from the strong axial crystal-fields due to the short V$^{4+}$-O$_2^-$ bond in the [VOCl$_4$]$^{2-}$ cluster. The obtained spin Hamiltonian parameters agree well with the experimental data and need fewer adjustable parameters than the previous studies. The covalency of the studied system is also discussed.
