Electrocapillary curves (surface tension $\gamma$ as a function of the electrode potential $E$) for a series of room-temperature ionic liquids (RTILs) were measured using a mercury dropping electrode with the drop-weight (drop-volume) technique. The curves $\gamma = f (E)$ for the Hg/RTIL interface have one maximum and may be approximated with a polynomial of sixth-order. There are no ‘humps’ in the curves. The interfacial tension of the Hg/RTIL system changes with potential $E$ in a monotonic way. The second derivative of $\gamma = f (E)$ leads to a polynomial of fourth order, indicating the capacitance of the Hg/RTIL interface. The potential of zero charge is within a relatively narrow range. The specific capacitance at the minimum is of the order $10 \mu$F/cm$^2$.

Key words: Ionic Liquid; Electrocapillary Curve.
