Crystals of $N$-3-pyridinyl-methanesulfonamide, PMSA (monoclinic, $P 2_{1} / c, a=5.6436(7)$ ), $b=$ $\left.33.875(4), c=8.3356(10) \AA, \beta=96.885(2)^{\circ}\right)$ contain two non-equivalent molecules differing considerably in their conformations. The structure is stabilized by a network of hydrogen bonds, the strongest one being between the pyridine N atom and the sulfonamide H atom. Crystals of trans-[Pt(PMSA) ${ }_{2} \mathrm{I}_{2}$ ] (monoclinic, $C 2 / c, a=22.912(2), b=5.2397(5), c=17.3376$ (17) A, $\beta=$ $\left.92.631(2)^{\circ}\right)$ contain centrosymmetric complex molecules in which PMSA is coordinated via the pyridine N atom, and Pt has a planar coordination. A system of hydrogen bonds of the types $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ links the complex molecules.

Key words: N-3-Pyridinyl-methanesulfonamide, Platinum(II), Crystal Structure

## Introduction

Farrell et al. established [1] that when the ammonia ligands in the molecule of the anticancer agent cisplatin, cis- $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\right]$, are replaced by planar ligands like pyridine, the cytotoxicity of the trans-isomers of the resulting complexes is comparable to that of cisplatin, while the cis-analogues are inactive. This finding lead to the development of the trans-platinum complexes with planar heterocyclic N -donor ligands as a new class of non-conventional platinum antitumor agents which retain their activity against cisplatinresistant cells [2-5].

The antitumor activity of sulfonamide derivatives $[6,7]$ and its relation with the processes of enzyme inhibition attract much attention in the last years. In this direction, the most studied targets of enzyme inhibition by sulfonamides are carbonic anhydrases [7], cyclooxygenase-2 [8, 9] and topoisomerases [10, 11]. Sulfonyl derivatives of pyridine and related heterocycles display versatile pharmacological activity based on the inhibition of carbonic anhydrases [7c] or cyclooxygenase-2 [8]. As shown by Supuran et al., [7c, 12] numerous metal complexes with sulfonamide ligands act as carbonic anhydrase inhibitors.

Fig. 1. Structural formulae of PMSA (1) and trans$\left[\mathrm{Pt}(\mathrm{PMSA})_{2} \mathrm{I}_{2}\right]$ (2).

Recently [13a], we studied the conformational features (by molecular mechanics and HF ab initio calculations) and infrared spectra of N-3-pyridinylmethanesulfonamide (PMSA). In continuation of our studies on the design of new platinum complexes as potential anticancer agents [14], a series of $\mathrm{Pd}(\mathrm{II})$ and $\mathrm{Pt}(\mathrm{II})$ complexes of PMSA was synthesized by us and characterized spectroscopically [13b]. The crystal structure of neither the free ligand nor its complexes has been studied so far.

Here we report the single crystal X-ray diffraction analysis of PMSA (1) and of the complex trans$\left[\mathrm{Pt}(\mathrm{PMSA})_{2} \mathrm{I}_{2}\right]$ (2) (Fig. 1) which appears to be the first structurally characterized metal complex of this ligand.

## Results and Discussion

Selected geometric parameters for the molecules of compounds $\mathbf{1}$ and 2 are collected in Table 1. A perspective view of the two crystallographically nonequivalent asymmetric molecules of the free ligand, $\mathbf{1 a}$ and $\mathbf{1 b}$, is shown in Fig. 2. The bond lengths and bond angles have the usual values compared with other N -aryl- (hetaryl-) substituted sulfonamides [15-18]; they are in satisfactory agreement with the theoretically calculated values (HF ab initio optimization of a single molecule with the $3-21 \mathrm{G}\left(^{*}\right)$ basis set) [13a]. The conformers 1a and 1b differ considerably with respect to the bond angles around the sulfonamide ni-

trogen atom. Thus, in 1a, the sulfonamide $\mathrm{N}(2)$ atom is almost fully planarized ( $s p^{2}$ hybridization, sum of the bond angles $358.9^{\circ}$ ), as predicted by the ab initio calculations [13a]. In 1b the sulfonamide $\mathrm{N}(2 \mathrm{~A})$ atom has a flattened-pyramidal configuration (sum of the bond angles $350.7^{\circ}$ ), like in other similar sulfonamides $[15,16]$. It is interesting to note that a complete planarization for the sulfonamide N atom has been observed in the $\mathrm{Zn}(\mathrm{II})$ complex of methanesulfonic acid hydrazide [19a], in distinct with the noncoordinated ligand [19b] and with its $\mathrm{Co}(\mathrm{II})$ and $\mathrm{Ni}(\mathrm{II})$ complexes [19c]. The second significant difference between the two independent PMSA molecules concerns the torsion angles about the $\mathrm{S}-\mathrm{N}(2)$ and $\mathrm{N}(2)-$

Fig. 3. Newman projections of: a) the $a b$ initio optimized minimum-energy conformation of an isolated PMSA molecule [13a] (note: here the numbering of $\mathrm{O}(1)$ and $\mathrm{O}(2)$ is the opposite of that used in [13a]); b) and c) the two independent molecules (1a and 1b, respectively) in the crystal structure of PMSA, d) The PMSA ligand in the crystal structure of trans$\left[\mathrm{Pt}(\mathrm{PMSA})_{2} \mathrm{I}_{2}\right](2)$. The first three letters in the notations of the conformations refer to the torsion angles $\mathrm{O}(1)-\mathrm{S}-\mathrm{N}(2)-\mathrm{C}(2)$, $\mathrm{O}(2)-\mathrm{S}-\mathrm{N}(2)-\mathrm{C}(2)$ and $\mathrm{C}(6)-\mathrm{S}-\mathrm{N}(2)-\mathrm{C}(2)$, respectively: $t=$ trans (torsion angle between 120 and $\left.180^{\circ}\right)$ ), $g-$ gauche with torsion angle between 0 and $60^{\circ}, G=$ gauche with torsion angle between 60 and $120^{\circ}$, with the corresponding sign. The remaining two letters refer to the torsion angles $\mathrm{S}-\mathrm{N}(2)-\mathrm{C}(2)-\mathrm{C}(1)$ and $\mathrm{H}(2)-\mathrm{N}(2)-\mathrm{C}(2)-\mathrm{C}(1)$, respectively $(E=$ entgegen, $Z=$ zusammen).

Fig. 4. A view of the packing of PMSA (1) within the unit cell, showing most of the hydrogen bonds.
$\mathrm{C}(2)$ bonds, giving rise to the different conformations $g^{-} t^{-} G^{+}, E^{+} Z^{-}$and $g^{-} t^{+} g^{+}, E^{-} Z^{+}$for $1 \mathbf{1 a}$ and $\mathbf{1 b}$, respectively, as shown in Fig. 3b, c. It is noteworthy that the $a b$ initio optimized structure of PMSA closely approaches that of $\mathbf{1 a}$. Thus, at qualitative level the conformations with respect to the $\mathrm{S}-\mathrm{N}$ bond are mirror images, and these with respect to the $\mathrm{N}-\mathrm{C}(2)$ bond are the same (Fig. 3a, b)

Fig. 4 shows the crystal packing of $\mathbf{1}$. The parameters of the hydrogen bond network for $\mathbf{1}$ and $\mathbf{2}$ are collected in Table 2. In both conformers 1a and 1b, the $\gamma$-hydrogen atoms of the pyridine ring form an intramolecular hydrogen bond with a sulfonyl oygen atom $(\mathrm{C}(3)-\mathrm{H}(3) \cdots \mathrm{O}(1)$ and $\mathrm{C}(3 \mathrm{~A})-\mathrm{H}(3 \mathrm{~A}) \cdots \mathrm{O}(1 \mathrm{~A})$, respectively). Two types of intermolecular hydrogen bonds connect the conformers 1a: between the

${ }^{\text {a }}$ Symmetry transformations: ${ }^{i} 1+x, 1 / 2-y, 1 / 2+z$; ${ }^{\text {ii }} x, 1 / 2-y$, $-1 / 2+z ;$ iii $1+x, y, z ;{ }^{\text {iv }}-x,-y, 1-z ;$ v) $-1+x, y,-1+z ;{ }^{\text {vi }} 1 / 2-$ $x, 3 / 2-y, 1-z$; vii $1 / 2-x,-1 / 2+y, 1 / 2-z$.
methyl and sulfonyl group $(\mathrm{C}(6)-\mathrm{H}(6 \mathrm{~A}) \cdots \mathrm{O}(1)$ and $\mathrm{C}(6)-\mathrm{H}(6 \mathrm{~B}) \cdots \mathrm{O}(2)$ ), and between a $\beta$-hydrogen atom of the pyridine ring and the sulfonyl group ( $\mathrm{C}(4)-$ $\mathrm{H}(4) \cdots \mathrm{O}(1))$. The conformers $\mathbf{1 b}$ form centrosymmetric hydrogen-bonded dimers of the type $\mathrm{DA}=\mathrm{AD}$ in expense of a pair of bonds $\mathrm{C}(6 \mathrm{~A})-\mathrm{H}(6 \mathrm{~A} 2) \cdots \mathrm{O}(2 \mathrm{~A})$ involving the methyl and sulfonyl groups. The two different conformers 1a and $\mathbf{1 b}$ are linked between each other by two types of hydrogen bonds - a short bond of the type $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ involving the imino hydrogen and the pyridine nitrogen atom $(\mathrm{H}(2) \cdots \mathrm{N}(1 \mathrm{~A})=$ $2.27 \AA$ and $\mathrm{H}(2 \mathrm{~A}) \cdots \mathrm{N}(1)=2.13 \AA)$, and a longer one $\mathrm{C}(1)-\mathrm{H}(1) \cdots \mathrm{O}(2 \mathrm{~A})(\mathrm{H}(1) \cdots \mathrm{O}(2 \mathrm{~A})=2.60 \AA$ A connecting a pyridine $\alpha$-hydrogen with a sulfonyl oxygen atom. Thus, the different conformations of the
molecules 1a and 1b give rise in the different intermolecular contacts.

The analysis of the IR spectra of $\mathbf{1}$ in solution and in the solid state gave us earlier [13a] the reason to assume the existence of a strong intermolecular hydrogen bond between the pyridine N atom and the acidic H atom of the sulfonamide group. The present X-ray structural analysis approved this suggestion.

A view of the complex molecule 2 is depicted in Fig. 5. The two PMSA ligands in trans-configuration are bound to the platinum by the pyridine nitrogen atom. The donor atoms are coplanar and form a $D_{2 \mathrm{~h}}$ tetragon $\left(\mathrm{N}_{2} \mathrm{I}_{2}\right)$ with the platinum in the center. The point group of the entire complex molecule is $C_{\mathrm{i}}$. The $\mathrm{Pt}-\mathrm{I}$ and $\mathrm{Pt}-\mathrm{N}$ bond lengths ( 2.607 and $2.032 \AA$, respectively) are in the ranges reported for trans-diiodo complexes of $\mathrm{Pt}(\mathrm{II})$ with pyridine-type ligands [2022]. The bond lengths and bond angles of the pyridine ring, as well as of the methanesulfonamide fragment in 2 are not affected considerably by the coordination. The sulfonamide nitrogen atom is fully planarized (sum of the bond angles $360^{\circ}$ ) like in 1a. The conformation of the sulfonamide residue in 2 ( $g^{-} t^{-} G^{+}, Z^{+} E^{-}$, Fig. 3d) differs, however, significantly as compared with the free ligand with respect to the torsion angles about the $\mathrm{N}(2)-\mathrm{C}(2)$ bond (Table 1$)$. This could be a result of the different type of hydrogen bonding (vide infra).

Like in other complexes of the type trans- $\left[\mathrm{ML}_{2} \mathrm{X}_{2}\right]$ ( $\mathrm{M}=\mathrm{Pt}, \mathrm{Pd} ; \mathrm{L}=$ pyridine-like ligand; $\mathrm{X}=\mathrm{Cl}, \mathrm{Br}, \mathrm{I}$ ) [1b, 20-27], the planes of the pyridine rings are not perpendicular to the coordination plane, but are rotated in the opposite directions, the dihedral angles being 69 and $-69^{\circ}$. The experimentally established geomet-

Fig. 6. A view of the extended hydrogen bonding network of trans $-\left[\mathrm{Pt}(\mathrm{PMSA})_{2} \mathrm{I}_{2}\right](\mathbf{2})$ along the $b$ axis.
ric parameters for the coordination node of $\mathbf{2}$ appeared quite similar to the values ascribed to them in [13b] for the purposes of the normal coordinate analysis and the interpretation of the far IR spectrum of the complex.

The crystal packing of $\mathbf{2}$ is presented in Fig. 6. The $\mathrm{O}(1)$ atom forms an intraligand hydrogen bond with $\mathrm{H}(1)$ atom of the pyridine ring. The complex molecules are connected centrosymmetrically via two couples of hydrogen bonds of the pattern $\mathrm{DA}=\mathrm{AD}$. The first couple involves the methyl group and the $\mathrm{O}(1)$ atom $(\mathrm{C}(6)-\mathrm{H}(6 \mathrm{~B}) \cdots \mathrm{O}(1))$, and the second one (the shorter) - the imino-hydrogen and $\mathrm{O}(2)$ atom ( $\mathrm{N}(2)-$ $\mathrm{H}(2) \cdots \mathrm{O}(2)$ ).

## Conclusion

The single crystal X-ray diffraction analysis of the pharmacologically interesting compounds PMSA and trans- $\left[\mathrm{Pt}(\mathrm{PMSA})_{2} \mathrm{I}_{2}\right]$ confirmed most of the conclusions regarding their structure, made earlier [13] on the basis of computational and spectroscopic results. The existence of a strong intermolecular hydrogen bond between the pyridine nitrogen and the sulfonamide hydrogen atom, previously suggested from the IR spectra of PMSA, was now proved by the X-ray analysis. Hydrogen-bonded assemblies of this type are of interest for supramolecular chemistry and crystal engineering [28], and could be related to molecular crystals with increased solid-state electric conductivity [29].

## Experimental Section

The ligand PMSA (1) was prepared from methanesulfonylchloride and 3-aminopyridine by the method of Jones

Table 3. Crystal data and structure refinement for compounds 1 and $2^{*}$.

| Compound | 1 | 2 |
| :---: | :---: | :---: |
| Empirical formula | $\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{~N}_{2} \mathrm{O}_{2} \mathrm{~S}$ | $\mathrm{C}_{12} \mathrm{H}_{16} \mathrm{I}_{2} \mathrm{~N}_{4} \mathrm{O}_{4} \mathrm{PtS}_{2}$ |
| $M$ | 172.21 | 793.31 |
| $T[\mathrm{~K}]$ | 293(2) | 293(2) |
| $\lambda$ [ $\AA$ ] | 0.71073 | 0.71073 |
| Crystal system | monoclinic | monoclinic |
| Space group | $P 2_{1} / c$ (No 14) | $C 2 / c$ (No 15) |
| $a[\AA]$ | 5.6436(7) | 22.912(2) |
| $b$ [ $\AA$ ] | 33.875(4) | 5.2397(5) |
| $c[\AA]$ | 8.3356(10) | 17.3376(17) |
| $\beta$ [deg] | 96.885(2) | 92.631(2) |
| $V\left[\AA^{3}\right]$ | 1582.1(3) | 2079.2(3) |
| Z | 8 | 4 |
| $D_{\text {calcd }}\left[\mathrm{Mg} \mathrm{m}{ }^{-3}\right]$ | 1.446 | 2.534 |
| $\mu\left[\mathrm{mm}^{-1}\right]$ | 0.359 | 9.942 |
| $F(000)$ | 720 | 1456 |
| Crystal size, mm | $0.3 \times 0.4 \times 0.5$ | $0.4 \times 0.4 \times 0.3$ |
| $\theta$ Range for data coll. [deg] | 2.40 to 26.37 | 1.78 to 26.37 |
| Limiting indices $h, k, l$ | $\begin{aligned} & -7 \leq h \leq 7 \\ & -42 \leq k \leq 42 \\ & -10 \leq l \leq 10 \end{aligned}$ | $\begin{aligned} & -28 \leq h \leq 28 \\ & -6 \leq k \leq 6 \\ & -21 \leq l \leq 21 \end{aligned}$ |
| Reflections collected | 12360 | 7868 |
| Independent reflections | 3207 | 2123 |
| $R_{\text {int }}$ | 0.0473 | 0.0605 |
| Refinement method | $\begin{aligned} & \text { - Full-r } \\ & \text { - least-s } \end{aligned}$ | atrix-block uares on $F^{2}$ |
| Data / restraints / params. | 3207 / 0 / 263 | 2123/0/144 |
| Goodness-of-fit on $F^{2}$ | 1.237 | 1.071 |
| Final $R$ Indices ( $I>2 \sigma(I)$ ) | $\begin{aligned} & R_{1}=0.0803 \\ & w R_{2}=0.1546 \end{aligned}$ | $\begin{aligned} & R_{1}=0.0452 \\ & w R_{2}=0.0869 \end{aligned}$ |
| $R$ Indices (all data) | $\begin{aligned} & R_{1}=0.1014 \\ & w R_{2}=0.1629 \end{aligned}$ | $\begin{aligned} & R_{1}=0.0603 \\ & w R_{2}=0.0916 \end{aligned}$ |
| Largest diff. peak and hole [ $\mathrm{e} \AA^{-3}$ ] | $\begin{aligned} & 0.480 \\ & \text { and }-0.346 \end{aligned}$ | $\begin{aligned} & 1.185 \\ & \text { and }-1.240 \end{aligned}$ |

* Crystallographic data for the structures have been deposited with the Cambridge Crystallographic Data Centre, CCDC-229268 and CCDC-229269. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (Fax: int.code +(1223)336-033; e-mail for inquiry: fileserv@ccdc.cam.ac.uk).
and Katritzky [30], and purified with charcoal [13a]. Crystal suitable for X-ray diffraction was selected from the crystalline mass obtained after the recrystallization of the product from hot water. Latter we found that well-formed, large (up to 7 mm ) crystals of PMSA can be obtained by long concentration at room temperature of a solution of the compound in a methanol water (2:1) mixture.

The complex trans- $\left[\mathrm{Pt}(\mathrm{PMSA})_{2} \mathrm{I}_{2}\right]$ (2) was synthesized by reacting $\left[\mathrm{Pt}(\mathrm{PMSA})_{4}\right] \mathrm{Cl}_{2}$ and KI in $N, N$-dimethylformamide, and recrystallizing the crude product from acetone [13b]. Crystal specimens for X-ray diffraction were obtained as follows. $5-7 \mathrm{mg}$ of the recrystallized product were dissolved in 2 ml of hot acetone, and the solution was carefully layered over carbon tetrachloride ( $c a .5 \mathrm{ml}$ ) in a short tube. The tube was stoppered, and avoiding shaking was left
in a refrigerator $\left(0^{\circ} \mathrm{C}\right)$. After $7-10$ days the yellow crystals were collected on a filter, washed with ether and dried in vacuo.
X-ray diffraction data were collected on a Bruker Smart Apex diffractometer with graphite-monochromated $\mathrm{Mo}-\mathrm{K}_{\alpha}$ radiation in the $\omega-2 \theta$ mode [31,32]. Cell constants were determined by using 25 reflections in the range $2.40<$ $\theta<27.18^{\circ}$ and $2.35<\theta<26.57^{\circ}$ for 1 and 2, respectively. Lorentz and polarization effects were corrected. Data reduction and analysis were carried out with the Bruker Smart programs. The structure was solved by direct methods (program SHELXS97) and refined by the full-matrix least-squares method on all $F^{2}$ data using the WinGX version of SHELXL97 programs [31,32]. Anisotropic thermal

parameters were used for all non-hydrogen atoms. All hydrogen atoms for $\mathbf{1}$ and 2 were located through Fourierdifference synthesis, except $\mathrm{N}(2)-\mathrm{H}$ for 2 was set in calculated position. Molecular graphics were performed using PLATON2001 [33]. A summary of the crystal data, experimental details and refinement results is presented in Table 3.
