Dedicated to Professor Gerhard Thiele on the occasion of his 70th birthday

Single crystals of light violet $Nd_2As_4O_9$ and yellow $Sm_2As_4O_9$ were obtained from the reactions of the respective lanthanide oxides with As_2O_3 in a NaCl flux at 850 °C in sealed silica ampoules. According to the structure determination, the triclinic compounds $(P\bar{1},Z=2,Nd/Sm:a=686.32(9)/680.92(9),b=763.06(8)/756.4(1),c=954.8(1)/951.2(1)$ pm, $\alpha=96.83(1)^\circ/96.66(2)^\circ$, $\beta=103.78(2)^\circ/103.67(2)^\circ$, $\gamma=104.40(1)^\circ/104.35(2)^\circ$, R=10.0184/0.0282 (all data)) have to be formulated as $RE_4(As_2O_5)_2(As_4O_8)$ emphasizing the presence of both $As_2O_5^{4-}$ and cyclic $As_4O_8^{4-}$ anions. The $As_4O_8^{4-}$ anions show C_i symmetry and connect layers of the composition $\{^\infty_{\infty}[RE_2(As_2O_5)]_2\}^{4+}$ along the [001] direction. The lanthanide ions are in nine- and eightfold coordination, respectively.

Key words: Lanthanides, Arsenites, cyclo-Tetraarsenite Anion

Introduction

There has been considerable increase in the knowledge of rare earth compounds containing complex oxo-anions throughout the last years [1]. The lively interest that these compounds have attracted can be attributed to their diverse properties, ranging from magnetic and spectroscopic phenomena to the features of open framework structures. Among the plethora of compounds that has been synthesized the oxoselenates(IV) (selenites) seem to be of vital importance [2]. One reason is that the crystal structures of selenites are frequently non-centrosymmetric and that the non-linear optical effects (NLO) arising from the lack of inversion symmetry are strong due to the high polarizability of the anions [3-6]. Recently we have used the SeO₃²⁻ ion successfully to combine rare earth and transition metal ions in solid state compounds aiming at new magnetic and luminescent properties [7, 8]. We now extended our efforts towards oxo-arenates(III) (arsenites) because these anions are isomorphous with the selenite ions but their higher charge allows for other compositions. Unfortunately no simple arsenates(III) of the rare earth elements are known up to now, and only the O^{2-} and Cl^- containing species $RE_3OCl(AsO_3)_2$ (RE=La, Sm, Gd) have been reported [9]. Here we present the syntheses of the first compounds in the systems RE_2O_3/As_2O_3 and their unusual crystal structure.

Experimental Section

For the syntheses of $RE_2As_4O_9$ (RE=Nd, Sm) the oxides RE_2O_3 (RE=Nd, Sm) and As_2O_3 as well as NaCl as a flux were sealed in silica tubes. The molar ratio $RE_2O_3/As_2O_3/NaCl$ was 1:2:5. In a resistance furnace the ampoules were fired in a first step to 350 °C. After keeping this temperature for 24 h, it was raised to 850 °C within 35 h. After 24 h at this temperature the furnace was cooled down slowly at a rate of 10 °C/h. The reaction products contained plate shaped single crystals of the arsenites which are light violet in the case of neodymium and yellow for samarium. For each compound some crystals were glued on glass fibres and checked by orientation images taken on an image plate diffractometer (STOE IPDS). They showed the same triclinic unit cell, and for the best specimen of the neodymium and samarium compound, respectively, intensity data were

Table 1. Crystallographic data of $Nd_4(As_2O_5)_2(As_4O_8)$ and $Sm_4(As_2O_5)_2(As_4O_8)$

^a Crystallographic data (excluding structure factors) for the structure in this paper have been deposited with the Fachinformationszentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen. The data can be obtained on quoting the given CSD number.

collected with the same diffractometer. The structure was solved applying direct methods [10] and refined introducing anisotropic displacement factors for all atoms [11]. Absorption effects have been treated numerically [12, 13]. Crystallographic data and details of the measurement are summarized in the Tables 1-3.

Results and Discussion

The oxo-arsenates(III) RE $_2$ As $_4$ O $_9$ (RE = Nd, Sm) are the first representatives of compounds in the systems RE $_2$ O $_3$ /As $_2$ O $_3$ with RE being a rare earth element. Interestingly, in the crystal structures no simple AsO $_3$ ³⁻ ions were found but diarsenite groups, As $_2$ O $_5$ ⁴⁻, and the unusual tetrameric cyclic As $_4$ O $_8$ ⁴⁻ anions. Thus, the compounds are to be written as to Nd $_4$ (As $_2$ O $_5$) $_2$ (As $_4$ O $_8$) and Sm $_4$ (As $_2$ O $_5$) $_2$ (As $_4$ O $_8$). The occurence of As $_2$ O $_5$ ⁴⁻ ions is a well known feature in the crystal chemistry of oxoarsenates(III) [14], and in both compounds under discussion the anions show

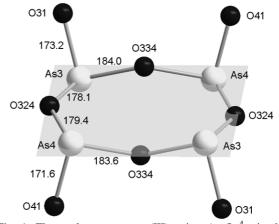

Fig. 1. The *cyclo*-tetraarsenate(III) anion $As_4O_8^{4-}$ in the crystal structures of $RE_4(As_2O_5)_2(As_4O_8)$ (RE=Nd, Sm). The anion has C_i symmetry and the bridging oxygen atoms O23 and O12 are situated slightly apart from the plane that is spanned by the four arsenic atoms. The bond distances (in pm) are given for the neodymium compound (*cf.* Table 3).

Table 2. Atomic positions and equivalent displacement parameters for $Nd_4(As_2O_5)_2(As_4O_8)$ and $Sm_4(As_2O_5)_2-(As_4O_8)$

essentially the distances and angles as previously described. The largest distances As-O within the group are found to the bridging oxygen atoms with values around 187 pm (Table 2), and the angles As-O-As are about 118°. The distances As-O to the terminal oxygen atoms vary between 171 and 178 pm, and the remarkable differences can be attributed to the different coordination of these atoms by the lanthanide ions. The angles O-As-O cover a large range from 89° up to 105°, again in good agreement with previous findings. The most interesting feature of the crystal structure of the new compounds is the tetrameric cycloarsenite anion, $As_4O_8^{\overline{4}-}$. To the best of our knowledge only one compound with a cyclo-tetraarsenite anion has been reported, namely the mineral stenhuggarite, CaFeSbAs₂O₇ [15]. In this mineral, however, the anion has a very different shape compared to the findings presented here: It shows the arsenic atoms in a tetrahe-

dral array (S_4 symmetry), while in the present case all arsenic atoms lie in a plane and the anion has C_i symmetry (Fig. 1). The bridging oxygen atoms within the tetramer are only slightly shifted from that plane by 14 pm (O334) and 57 pm (O324), respectively. The angles As-O-As are about 136° and the distances As-O to the bridging oxygen atoms range from 178 to 184 pm. The terminal and the bridging oxygen atoms form an-

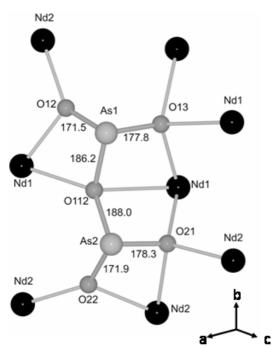

Fig. 2. Coordination of the $As_2O_5^{4-}$ groups by RE^{3+} ions in the crystal structures of $RE_4(As_2O_5)_2(As_4O_8)$ (RE=Nd, Sm). Distances are given in pm.

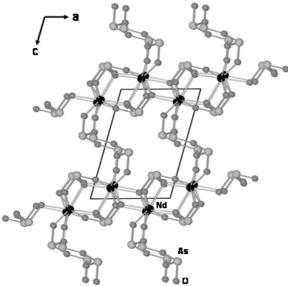

Fig. 3. Crystal structure of $RE_4(As_2O_5)_2(As_4O_8)$ (RE = Nd, Sm). Layers of the composition $\{{}^2_\infty[RE_2(As_2O_5)]_2\}^{4+}$ are stacked in the [001] direction and linked by $As_4O_8^{4-}$ ions. In the [010] direction open channels are formed that incorporate the lone electron pairs of the arsenic atoms.

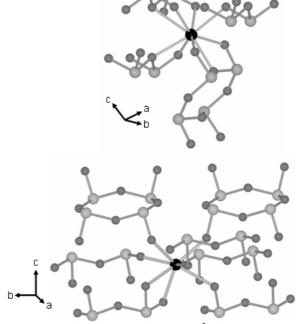

Fig. 4. Coordination of the $RE(1)^{3+}$ (on top) and $RE(2)^{3+}$ ions (at bottom) in the crystal structures of $RE_4(As_2O_5)_2(As_4O_8)$ (RE=Nd,Sm).

gles with the arsenic atoms that are either around 100° or around 90° . These distances and angles are similar to the findings for the *cyclo*-tetraarsenite anion in CaFeSbAs₂O₇, despite of the different shape of the individual anions.

In the crystal structure of the two arsenites, the RE³⁺ ions are linked by the $As_2O_5^{4-}$ groups to layers of the compostion $\{{}^2_{\infty}[RE_2(As_2O_5)]_2\}^{4+}$. Within the layers, the diarsenite groups are coordinated by eight RE³⁺ ions, and also the bridging oxygen atoms of the anion are involved in the RE³⁺ coordination (Fig. 2). This leads to relatively short RE³⁺-RE³⁺ distances of 367 pm for the neodymium and 363 pm for the samarium compound. The $\{{}^2_{\infty}[RE_2(As_2O_5)]_2\}^{4+}$ layers are stacked in the [001] direction, and are connected by the *cyclo*-tetraarsenite anions (Fig. 3).

In this way the latter are coordinated by six RE^{3+} ions via the terminal oxygen atoms and two of the four bridging oxygen atoms. For the two crystallographically different RE^{3+} ions, $RE(1)^{3+}$ and $RE(2)^{3+}$, coordination numbers of nine and eight arise. $RE(1)^{3+}$ is surrounded by three $As_2O_5^{4-}$ ions and one $As_4O_8^{4-}$ group, the diarsenite ions being mono-, di, and tri-dentate, and the *cyclo*-tetraarsenite anions be-

ing tridentate (Fig. 4). The [REO₉] polyhedron has the shape of a distorted tricapped trigonal prism. RE(2)³⁺ is surrounded by four monodentate and one chelating $As_2O_5^{4-}$ groups as well as by two monodentate $As_4O_8^{4-}$ ions leading to a square anti-prismatic [REO₈] polyhedron (Fig. 4).

As often observed in crystal structures involving ions with s^2 configuration, a prominent stereochemical influence of the lone electron pairs is observed. In the structures of $Nd_4(As_2O_5)_2(As_4O_8)$ and $Sm_4(As_2O_5)_2(As_4O_8)$ this leads to open channels along the [010] direction which obviously incorporate the electron pairs (Fig. 3).

Acknowledgements

This work has been supported by the Deutsche Forschungsgemeinschaft (Schwerpunktprogramm 1166, "Lanthanoidspezifische Funktionalitäten"). The authors would like to thank Mr. W. Saak for collecting the X-ray data.

Note. During the preparation of the manuscript it turned out that the samarium compound $Sm_4(As_2O_5)_2(As_4O_8)$ has been synthesized independently at the same time by the group of Prof. Th. Schleid, University Stuttgart, Germany [16].
