Received December 9, 2011
Dedicated to Professor Wolfgang Beck on the occasion of his $80^{\text {th }}$ birthday
The lanthanum(III)-decaborate $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ was synthesized under high-pressure/high-temperature conditions of 2.6 GPa and $750^{\circ} \mathrm{C}$ in a Walker-type multianvil apparatus. The single-crystal structure determination revealed that $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ is isotypic to $\mathrm{Pr}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$. $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ crystallizes monoclinically with four formula units in the space group $P 2_{1} / n$ with the lattice parameters $a=716.7$ (2), $b=1971.5(4), c=958.3(2) \mathrm{pm}$, and $\beta=93.7(1)^{\circ}$. The three-dimensional boron-oxygen framework consists of $\left[\mathrm{BO}_{4}\right]^{5-}$ tetrahedra and trigonal-planar $\left[\mathrm{BO}_{3}\right]^{3-}$ groups. The structure contains four crystallographically different lanthanum ions. Two of the ions are surrounded by 10 , one by 11 , and the fourth one by 12 oxygen anions. In addition to IR-spectroscopic investigations, DFT calculations were performed to support the assignment of vibrational bands.

Key words: High Pressure, Borate, Crystal Structure, DFT

## Introduction

The system La-B-O is represented by four compositionally different oxoborates with the formulae $\mathrm{LaBO}_{3}$ for $\lambda-\mathrm{LaBO}_{3}$ [1] and the high-temperature modification $\mathrm{H}-\mathrm{LaBO}_{3}$ [2], $\mathrm{LaB}_{3} \mathrm{O}_{6}$ for one normal pressure oxoborate [3] and two high-pressure modifications, namely $\gamma-\mathrm{LaB}_{3} \mathrm{O}_{6}$ [4] and $\delta-\mathrm{LaB}_{3} \mathrm{O}_{6}$ [5], $\mathrm{La}_{4} \mathrm{~B}_{14} \mathrm{O}_{27}$ [6], and $\mathrm{La}_{26} \mathrm{O}_{27}\left(\mathrm{BO}_{3}\right)_{8}$ [7]. Except for the two high-pressure modifications of the lanthanum-meta-borate $\gamma-\mathrm{LaB}_{3} \mathrm{O}_{6}$ and $\delta-\mathrm{LaB}_{3} \mathrm{O}_{6}$, all known lanthanum oxoborates are synthesized by heating of stoichiometric mixtures of $\mathrm{La}_{2} \mathrm{O}_{3}$ and $\mathrm{B}_{2} \mathrm{O}_{3}$ under ambient pressure conditions. As a common trend in high-pressure oxoborates, the boron atoms favor the fourfold coordination with increasing pressure. In the majority of cases, the trigonal-planar $\left[\mathrm{BO}_{3}\right]^{3-}$ groups transform into tetrahedral $\left[\mathrm{BO}_{4}\right]^{5-}$ groups at a pressure higher than 10 GPa . Beyond this threshold, only a few compounds are known which contain trigonal-planar $\left[\mathrm{BO}_{3}\right]^{3-}$ groups, e.g. $\mathrm{Ho}_{31} \mathrm{O}_{27}\left(\mathrm{BO}_{3}\right)_{3}\left(\mathrm{BO}_{4}\right)_{6}$ [8]. Additionally, our team observed that these tetrahedra, which are normally linked via common corners, can share common edges to realize denser structures $\left[R E_{4} \mathrm{~B}_{6} \mathrm{O}_{15}(R E=\mathrm{Dy}\right.$, Ho) [9-11] and $\alpha-R E_{2} \mathrm{~B}_{4} \mathrm{O}_{9}(R E=\mathrm{Sm}-\mathrm{Ho})$ ] [12-14]).

Furthermore, under high-pressure conditions the rareearth ions can show increased coordination numbers ( CN ), and also the coordination numbers of the oxygen atoms can be enhanced from two-fold coordinated $\left(\mathrm{O}^{[2]}\right)$ to three-fold coordinated $\left(\mathrm{O}^{[3]}\right)$. With the high-pressure/high-temperature synthesis of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$, we add a new compound to the existing lanthanum-oxoborates. This compound is isotypic to $\mathrm{Pr}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ [15]. In the following, we describe the synthesis, the single-crystal structure determination, IR spectroscopic investigations, and quantum-chemical calculations of harmonic vibrational frequencies of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$.

## Experimental Section

## Synthesis

The synthesis of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ was achieved under high-pressure/high-temperature conditions of 2.6 GPa and $750^{\circ} \mathrm{C}$ during experiments to synthesize new lanthanum fluoridoand fluoride borates. For the synthesis, a non-stoichiometric mixture of partially hydrolyzed $\mathrm{La}_{2} \mathrm{O}_{3}, \mathrm{LaF}_{3}$, and $\mathrm{B}_{2} \mathrm{O}_{3}$ (all chemicals from Strem Chemicals, Newburyport, USA, $99.9 \%$ ) in a molar ratio of $2: 1: 6$ was finely ground and filled into a boron nitride crucible (Henze BNP GmbH, HeBoSint ${ }^{\circledR}$ S100, Kempten, Germany). The crucible was
placed into an 18/11-assembly and compressed by eight tungsten carbide cubes (TSM-10, Ceratizit, Reutte, Austria). To apply the pressure, a 1000 t multianvil press with a Walker-type module (both devices from the company Voggenreiter, Mainleus, Germany) was used. The assembly and its preparation are described in refs. [1620]. The mixture of the starting materials was compressed to 2.6 GPa within 1 h and kept at this pressure. During the heating period, the temperature was increased to $750{ }^{\circ} \mathrm{C}$ in 10 min , kept there for 10 min , and lowered to $450{ }^{\circ} \mathrm{C}$ within 15 min , followed by quenching to r.t. The decompression of the assembly required three hours. The recovered octahedral pressure medium ( MgO , Ceramic Substrates \& Components Ltd., Newport, Isle of Wight, UK) was broken apart, and the sample was separated from the surrounding boron nitride crucible. The compound $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ was found in the form of colorless air-stable crystals.

All efforts to synthesize $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ under ambient pressure conditions were not successful. The high-temperature syntheses were performed in boron nitride crucibles (Henze BNP GmbH, HeBoSint ${ }^{\circledR}$ S100, Kempten, Germany) which were placed into a silica glass tube. This assembly was heated under ambient-pressure conditions in a tube furnace from the company Carbolite.

## Crystal structure analysis

The powder diffraction pattern was obtained in transmission geometry, using a Stoe Stadi $P$ powder diffractometer with $\operatorname{Ge}(111)$-monochromatized $\operatorname{Mo}_{\alpha 1}(\lambda=70.93 \mathrm{pm})$ radiation. The diffraction pattern showed reflections of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ and $\mathrm{LaF}_{3}$. Fig. 1 shows the experimental powder pattern that matches well with the theoretical pattern simulated from the single-crystal data. Small single crystals of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ were isolated by mechanical fragmentation.

Fig. 1. Experimental powder pattern (top) and the pattern of $\mathrm{LaF}_{3}$ (top, lines), compared with the theoretical powder pattern of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ (bottom), simulated from single-crystal data.

The single-crystal intensity data were collected at r.t. using a Nonius Kappa-CCD diffractometer with graphite-monochromatized $\mathrm{Mo} K_{\alpha}$ radiation ( $\lambda=71.073 \mathrm{pm}$ ). A semiempirical absorption correction based on equivalent and redundant intensities (Scalepack [21]) was applied to the intensity data. All relevant details of the data collection and evaluation are listed in Table 1. According to the systematic extinctions, the monoclinic space group $P 2_{1} / n$ was derived. Because $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ is isotypic to $\mathrm{Pr}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ [7], the structural refinement was performed via the positional parameters of $\mathrm{Pr}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ as starting values [SHELXL-97 [22,23] (full-matrix least-squares on $F^{2}$ )]. All atoms were refined with anisotropic displacement parameters, and the final difference Fourier syntheses did not reveal any significant peaks in the refinement. Tables $2-5$ list the positional parameters, anisotropic displacement parameters, and interatomic distances.

Further details of the crystal structure investigation may be obtained from Fachinformationszentrum Karlsruhe, 76344 Eggenstein-Leopoldshafen, Germany (fax: +49-7247-808-666; e-mail: crysdata@fiz-karlsruhe.de, http://www.fizkarlsruhe.de/request_for_deposited_data.html) on quoting the deposition number CSD-424159.

Table 2. Atomic coordinates (Wyckoff positions $4 e$ for all atoms) and equivalent isotropic displacement parameters $U_{\text {eq }}\left(\AA^{2}\right)$ of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ (space group: $P 2_{1} / n$ ) with standard deviations in parentheses. $U_{\mathrm{eq}}$ is defined as one third of the trace of the orthogonalized $U_{i j}$ tensor.

## Vibrational spectra

The FTIR-ATR (Attenuated $T$ otal Reflection) spectra of single crystals were measured with a Bruker Vertex 70 FTIR spectrometer (spectral resolution $4 \mathrm{~cm}^{-1}$ ), equipped with an MCT (mercury cadmium telluride) detector and attached to a Hyperion 3000 microscope in the spectral range of 600 $4000 \mathrm{~cm}^{-1}$. As mid-infrared source, a Globar (silicon carbide) rod was used. A frustum-shaped germanium ATR crystal with a tip diameter of $100 \mu \mathrm{~m}$ was pressed on the surface of the borate crystal, which crushed it into small pieces of $\mu \mathrm{m}$-size. 32 scans of the sample were acquired. A correction for atmospheric influences using the Opus 6.5 software was performed. A mean refraction index of the sample of 1.6 was assumed for the ATR correction.

## DFT calculations

In addition to the experimentally recorded IR spectrum, quantum-chemical computations of harmonic vibrational frequencies were performed using the Crystal 09 program [24-26]. An important step of a quantum-mechanical calculation of frequencies is the choice of an adequate basis set. A compromise has to be found balancing computational effort and accuracy of the results. To reduce the computational effort, a basis set with an effective core potential (ECP) for the lanthanum atoms was chosen. The
best basis set was found based on geometry optimizations and calculations of harmonic vibrational frequencies of the high-pressure modification $\delta-\mathrm{LaB}_{3} \mathrm{O}_{6}$ [6]. To consider the meta-stability of high-pressure modifications, the cell volume was kept constant during the geometry optimization. Out of these results, a well tested basis set for barium [27] including HAYWSC [28-30] for the inner electrons, was modified by adding one electron. All-electron basis sets were employed for boron [31] and oxygen [32]. All calculations were performed with the PBESOL functional [33] for the correlation- and exchange-functionals. The test calculation for $\delta-\mathrm{LaB}_{3} \mathrm{O}_{6}$ using the above settings yielded a deviation less than one percent for the lattice parameters and atom positions. The PBE functional [34] was also tested for $\delta-\mathrm{LaB}_{3} \mathrm{O}_{6}$ and $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$, but poorer results were obtained. The overall computation time for the calculations of harmonic vibrational frequencies of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ amounted to four weeks on a node with 16 Opteron dual-core 2.8 GHz processors.

## Results and Discussion

## Synthetic conditions and reproducibility

All efforts to receive $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ from a stoichiometric mixture of the pure oxides $\mathrm{La}_{2} \mathrm{O}_{3}$ and $\mathrm{B}_{2} \mathrm{O}_{3}$ under normal- and high-pressure conditions were not successful. Obviously, additional $\mathrm{LaF}_{3}$ in the role

${ }^{\mathrm{a}}$ n. p. $=$ normal pressure.
of a flux during the synthesis is necessary to yield $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ as the main product. A detailed schedule of all performed syntheses, including educts, reaction conditions, and products is shown in Table 6. The normal-pressure experiments yielded $\alpha-\mathrm{LaB}_{3} \mathrm{O}_{6}$ and $\lambda-\mathrm{LaBO}_{3}$. Under high-pressure/high-temperature conditions, the lanthanum-meta-borates $\alpha-\mathrm{LaB}_{3} \mathrm{O}_{6}$ and $\delta$ $\mathrm{LaB}_{3} \mathrm{O}_{6}$ were the main-products while syntheses at higher temperatures led to $\alpha-\mathrm{LaB}_{3} \mathrm{O}_{6}$. This systematic approach led to the conclusion that the new lanthanum oxoborate $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ is just synthesizable in a small range of pressure and temperature using $\mathrm{LaF}_{3}$ as a flux material.

## Crystal structure of $L a_{4} B_{10} O_{21}$

The structure of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ is composed of trigonal $\left[\mathrm{BO}_{3}\right]^{3-}$ and tetrahedral $\left[\mathrm{BO}_{4}\right]^{5-}$ groups. Eight of ten crystallographically different boron atoms are coordinated by four oxygen ions. The $\left[\mathrm{BO}_{3}\right]^{3-}$ and $\left[\mathrm{BO}_{4}\right]^{5-}$ groups are linked to a highly condensed threedimensional network. Fig. 2 shows the structure along

Fig. 2 (color online). Projection of the crystal structure of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ along [ $\overline{1} 00$ ].

Fig. 3 (color online). Crystal structure of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ as viewed along [ $00 \overline{1}]$, showing the boron-oxygen network and the two different building units.
$[100]$. The $\left[\mathrm{BO}_{3}\right]^{3-}$ and $\left[\mathrm{BO}_{4}\right]^{5-}$ groups form corrugated layers in the $a b$ plane, which are marked by differently colored tetrahedra. These layers are linked via corner-sharing $\left[\mathrm{BO}_{4}\right]^{5-}$ groups. Each layer consists of two different building blocks. The building blocks and their linkage to the layers are illustrated in Fig. 3. The first building block (Fig. 3, top left) consists of ten tetrahedral $\left[\mathrm{BO}_{4}\right]^{5-}$ groups. Six tetrahedral groups form a so called central "vierer" ring and two "dreier" rings [35]. On each "dreier" ring, two $\left[\mathrm{BO}_{4}\right]^{5-}$ tetrahedra are added. The second building block (Fig. 3, top right) is built up similarly to the first building block
and consists of four trigonal $\left[\mathrm{BO}_{3}\right]^{3-}$ and six tetrahedral $\left[\mathrm{BO}_{4}\right]^{5-}$ groups. The six tetrahedral groups form the same central "vierer" ring and two "dreier" rings like the first building block. The $\left[\mathrm{BO}_{3}\right]^{3-}$ groups substitute the four $\left[\mathrm{BO}_{4}\right]^{5-}$ tetrahedra on the outside of the central rings. The two building blocks are linked via the outer $\left[\mathrm{BO}_{4}\right]^{5-}$ tetrahedra and $\left[\mathrm{BO}_{3}\right]^{3-}$ groups.

The boron-oxygen distances inside the eight distinguishable $\left[\mathrm{BO}_{4}\right]^{5-}$ groups vary between 142.6(5) (B7O 12 ) and $155.9(6) \mathrm{pm}$ (B6-O19) with a mean value of 148.0 pm . The trigonal groups show boron-oxygen distances of $136.0(6)-140.3(5) \mathrm{pm}$ with a mean value of 137.4 pm . The mean values of the boron-oxygen distances correspond well with the known average values for $\mathrm{B}-\mathrm{O}$ distances in $\left[\mathrm{BO}_{4}\right]^{5-}$ and $\left[\mathrm{BO}_{3}\right]^{3-}$ groups [36-38].

The four crystallographically distinguishable rareearth cations are located in channels between the layers (Fig. 2). The rare-earth ions La1 and La2 are coordinated by 10 oxygen atoms between 246.1(3) and 280.3(3) pm for La1 and between 246.9(3) and $282.2(3) \mathrm{pm}$ for La 2 . These values fit well to the $\mathrm{La}-\mathrm{O}$ distances of $\alpha-\mathrm{La}\left(\mathrm{BO}_{2}\right)_{3}[d(\mathrm{La}-\mathrm{O})=243-$ $285 \mathrm{pm}(\mathrm{CN}=10)$ ] [39] and to the tenfold coordinated lanthanum ions in $\mathrm{La}_{4} \mathrm{~B}_{14} \mathrm{O}_{27}[d(\mathrm{La}-\mathrm{O})=$ $240.9-285.1 \mathrm{pm}(\mathrm{CN}=10)$ ] [5]. The third $\mathrm{La}^{3+}$ ion (La3) is coordinated by 11 oxygen atoms in the range $233.9(3)-308.2(3) \mathrm{pm}$. The fourth lanthanum ion (La4) in $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ is surrounded by 12 oxygenatoms with lanthanum-oxygen distances of 244.2(3)308.8(3) pm. All distances are listed in the Tables 4 and 5 .

The bond-valence sums of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ were calculated from the crystal structure for all ions, using the bond-length/bond-strength concept ( $\Sigma V$ ) [40, 41]. The calculation revealed values of: +2.93 (La1),+3.23 $(\mathrm{La} 2),+3.06(\mathrm{La} 3)$, and $+3.04(\mathrm{La} 4)$ which fit well for the formal ionic charges. For the boron ions, the values vary between 2.95 and 3.04 . The oxygen ions show values from -1.86 to -2.24 .

Furthermore, the Maple values (MAdelung Part of Lattice Energy) [42-44] of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ were calculated to compare them with the MAPLE values received from the summation of the binary components $\mathrm{La}_{2} \mathrm{O}_{3}$ [45] and the high-pressure modification $\mathrm{B}_{2} \mathrm{O}_{3}$-II [46]. The value of $138125 \mathrm{~kJ} \mathrm{~mol}^{-1}$ was obtained in comparison to $138160 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (deviation $=0.03 \%$ ), starting from the binary oxides $\left[\mathrm{La}_{2} \mathrm{O}_{3}\right.$ $\left(14234 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)+\mathrm{B}_{2} \mathrm{O}_{3}-\mathrm{II}\left(21938 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)$ ].

Despite their isotypy, there is one large difference in the structures of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ and $\mathrm{Pr}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$. Table 7 compares the unit cells, the coordination numbers of the rare-earth metal ions, and the bond lengths. A closer look at the lattice parameters $a, b$, and $c$ reveals the typical rise due to the higher ionic radius of $\mathrm{La}^{3+}$. The coordination numbers of $R E 1, R E 2$, and $R E 4$ $(R E=\mathrm{La}, \mathrm{Pr})$ are equivalent. In contrast, the coordination number of $R E 3$ is different. Fig. 4 shows the relationship between the $R E-\mathrm{O}$ distances in $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ and $\mathrm{Pr}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$. As expected, the $R E-\mathrm{O}$ distances in $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ are higher, because of the larger ionic radius of $\mathrm{La}^{3+}$. For RE3, the distance to the eleventh oxygen atom differs widely. In contrast to the trend, the oxygen O 1 b is closer to the metal ion in $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$.

Fig. 4 (color online). RE-oxygen distances of Pr3 and La3. Due to the larger ionic radius of $\mathrm{La}^{3+}$, the distances $\mathrm{La}-\mathrm{O}$ are larger except for the oxygen atom O1b. This deviation yields to a higher coordination number of La3 than Pr 3 in $R E_{4} \mathrm{~B}_{10} \mathrm{O}_{21}(R E=\mathrm{La}, \mathrm{Pr})$.

Fig. 5 (color online). Coordination spheres of the RE3 ions in $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ (left) and $\mathrm{Pr}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ (right).

Hence, the coordination number of La3 is higher than the coordination number of Pr3. Fig. 5 shows the different coordination spheres of the ions La3 and Pr3.

## Vibrational spectroscopy

The spectrum of the FTIR-ATR measurement of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ is displayed in Fig. 6. The assignments of the vibrational modes are based on a comparison with the experimental data of borate glasses and crystals, containing trigonal $\left[\mathrm{BO}_{3}\right]^{3-}$ and tetrahedral $\left[\mathrm{BO}_{4}\right]^{5-}$ groups [47-51], and on quantum-mechanical calculations. For borates in general, bands in the region of $800-1100 \mathrm{~cm}^{-1}$ usually apply to stretching modes of boron which is tetrahedrally coordinated to oxygen atoms $[52,53]$. Absorption bands at $1200-1450 \mathrm{~cm}^{-1}$ are expected for borates containing $\left[\mathrm{BO}_{3}\right]^{3-}$ groups $[1,54]$.

In the FTIR spectrum of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$, several groups of absorption bands of the boron-oxygen tetrahedra were detected between 680 and $1135 \mathrm{~cm}^{-1}$. The $\left[\mathrm{BO}_{3}\right]^{3-}$ modes are found between 1250 and $1450 \mathrm{~cm}^{-1}$. Furthermore, no OH or water bands could be detected in the range of 3000 to $3600 \mathrm{~cm}^{-1}$.

Fig. 6 (color online). FT-IR reflectance spectrum of a single crystal of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ (black) and calculated vibrational bands (red lines).

${ }^{\mathrm{a}} \mathrm{s}=$ stretching; $\mathrm{b}=$ bending; in parentheses: pairs of bonded atoms with large relative motion between them; subscript $\mathrm{BO}_{3}$ and $\mathrm{BO}_{4}$ refer to the group in which the boron is located.

In the case of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$, one must consider that all boron-oxygen units are linked to other boron-oxygen units. Hence, every normal mode inside of one boronoxygen unit induces motions in the connected units. Nevertheless, quantum-chemical calculations (vide infra) of harmonic vibrational frequencies could be useful to assign vibrations of excited groups. Fig. 6 shows the experimental IR spectrum in the range of $600-$ $1500 \mathrm{~cm}^{-1}$ and the calculated modes.

Quantum-mechanical calculations of harmonic vibra-
tional frequencies
Quantum-mechanical calculations of theoretical vibrational modes of large systems like $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ which contain several heavy atoms like lanthanum are rare. The calculation yields 97 theoretically possible IR-active and 97 Raman-active modes in the
range $600-1500 \mathrm{~cm}^{-1}$. Furthermore, the intensities of the IR-active modes were calculated. All calculated vibrational modes show a shift of about $20 \mathrm{~cm}^{-1}$ to higher wave numbers. This deviation results out of the approximations in the DFT method, the relatively low convergence for the energy $\left(10^{-7} \mathrm{E}_{h}\right)$ and the calculation of just one unit cell. Calculations of larger systems (supercells of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ ) were not possible. Moreover, the calculation did not consider the temperature ( 297 K for the experiment), and the addition of two Gaussian peaks in the experimental spectrum led to a shift of the maxima.

The large number of theoretical modes prevents a complete assignment of all vibrational modes. The most intensive bands were evaluated, compared with the experimental spectrum and listed in Table 8. In the assignment, the highly condensed boron-oxygen framework must be considered. An exclusive stretching or bending motion inside a building unit is not possible. As expected, in the region of higher wave numbers the excitation happened inside the trigonal $\left[\mathrm{BO}_{3}\right]^{3-}$ groups as boron-oxygen stretching. At $1223 \mathrm{~cm}^{-1}$ in the calculated spectrum and at $1210 \mathrm{~cm}^{-1}$ in the experimental spectrum, the first stretching modes inside of the $\left[\mathrm{BO}_{4}\right]^{5-}$ tetrahedra are observed. This is about 100 wave numbers higher than expected for tetrahedral $\left[\mathrm{BO}_{4}\right]^{5-}$. Bands at lower wave numbers result from motions of boron and oxygen in-
side of tetrahedral $\left[\mathrm{BO}_{4}\right]^{5-}$ groups. The assignment to $\left[\mathrm{BO}_{4}\right]^{5-}$ or $\left[\mathrm{BO}_{3}\right]^{3-}$ groups took place to those boron-oxygen units in which the excited bond is located. Bands at lower wave numbers become more and more dominated by bending modes. In the region $940-$ $980 \mathrm{~cm}^{-1}$ (calculated at $963 \mathrm{~cm}^{-1}$ ), the first bending mode of a boron-lanthanum-oxygen unit is observed. The first stretching vibrations of the type $s(\mathrm{La}-\mathrm{O})$ is located at $721 \mathrm{~cm}^{-1}$ in the calculated spectrum.

## Conclusions

With the synthesis of $\mathrm{La}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$, the first isotypic compound to $\operatorname{Pr}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ was found and characterized. In accordance with the relatively mild applied pressure of 2.6 GPa , the structure consists of $\left[\mathrm{BO}_{4}\right]^{5-}$ tetrahedra and $\left[\mathrm{BO}_{3}\right]^{3-}$ groups. $80 \%$ of the boron-oxygen units are represented by $\mathrm{BO}_{4}$ tetrahedra. The synthesis of the missing isotypic compound in the series $R E_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$ between lanthanum and praseodymium, $\mathrm{Ce}_{4} \mathrm{~B}_{10} \mathrm{O}_{21}$, will be subject of our future efforts.

## Acknowledgements

Special thanks go to Univ.-Prof. Dr. R. Stalder (University of Innsbruck) for performing the IR measurements and Prof. Dr. D. Johrendt (Ludwig-Maximilians University Munich) for the fruitful discussions concerning the DFT calculations. The research was funded by the Austrian Science Fund (FWF): P 23212-N19.

[35] The naming of rings of structural elements was coined by F. Liebau (F. Liebau, Structural Chemistry of Silicates, Springer, Berlin, 1985) and is derived from German numbers, $e . g$. the terms "dreier" rings and "vierer" rings are derived from the words "drei" respectively "vier", which mean three and four. However, the terms "dreier" ring and "vierer" ring do not mean a threemembered or four-membered ring, but rather a ring with three or four tetrahedral centers (B) and three or four electronegative atoms ( O ).
