Polypore Fungi, White Rot, Molecular Systematics, ITS1 Region, *Ganoderma*

The systematic affinities of *Ganoderma* have largely been resolved in the extensive publications of Moncalvo and coworkers (Moncalvo *et al.*, 1995a, b; Hsieh *et al.*, 1996). The present communication adds further sequences of the ITS1 region of *Ganoderma* isolates from Poland and corrects some of the classifications of *Ganoderma* species. The sequence data indicate that *G. australe* and *G. adspersum* are different species. Both morphological and molecular data are in accord with an interspecific separation of *G. pfeifferi* and *G. resinaceum*. The ITS1 region is particularly suited for the taxonomic segregation of *Ganoderma* by molecular methods.
