Biotic Stress, Photosynthetic Electron Transport, Photosystem II, Thermoluminescence, Virus Infection

Changes of thermoluminescence characteristics as well as the \(O_2\)-evolving capacity was analysed in chloroplasts isolated from \textit{Nicotiana benthamiana} infected with pepper and paprika mild mottle viruses and their chimeric hybrids. The electron transport activity in thylakoids of virus-infected plants was inhibited and could be restored by adding DPC or \(Ca^{2+}\) which indicated that the virus infection altered the oxygen-evolving complex. In thermoluminescence characteristics of plants infected with either viruses, the first well defined response was a shift in the peak position of the B band from 20 °C to 35 °C corresponding to \(S_3(S_2)Q_B^-\) and \(S_2Q_B^-\) charge recombinations, respectively, which showed an inhibition in the formation of higher \(S\) states in the water splitting system. Simultaneously, a new band appeared around 70 °C due to chemiluminescence of lipid peroxidation. Further progress of the viral infection dramatically decreased the intensity of bands originated from charge recombinations with a concomitant increase of the band at 70 °C indicating the general oxidative breakdown of injured thylakoids.
