Cytotoxicity-guided fractionation of the alcohol extract of the brown alga, Cystoseira myrica, afforded four new cytotoxic hydroazulene diterpenes, dictyone acetate (2), dictyol F monoacetate (4), isodictytriol monoacetate (6), and cystoseirol monoacetate (8), together with two known cytotoxic hydroazulene diterpenes, pachydictyol A (1) and dictyone (3). The constitution of each isolated compound has been determined on the basis of spectroscopic and chemical evidence.

Key words: Cystoseira, Cytotoxic, Hydroazulenes

Introduction

Marine plants have yielded a variety of secondary metabolites that possess novel chemical structures and interesting pharmacological activities (Stonik and Elyalov, 1986). Recently, researchers have described a wide range of biological activities for algal compounds including anti-HIV, anticoagulant, anticonvulsant, anti-inflammatory, antineoplastic, and cytotoxic activities (Lincoln et al., 1991). A number of diterpenes and sterols have been isolated from the brown algae belonging to the genus Cystoseira (Banaigs et al., 1983, Francisco et al., 1977, Combaut et al., 1980).

In a search for bioactive substances from marine brown algae, we collected Cystoseira myrica at El-Zafrana, Gulf of Suez. Cytotoxicity-guided fractionation of the alcohol extract afforded four new cytotoxic hydroazulene diterpenes as well as two known ones. The chemotaxonomic implication of these findings is also discussed.

Results and Discussion

An ethanolic extract of the brown alga Cystoseira myrica was fractionated on silica gel using a gradient of hexane-ether as gradient solvent. The fractions were monitored by cytotoxicity bioassays using three proliferating mouse cell lines: NIH3T3, SSVNIH3T3, and KA3IT to afford, in order of elution, six compounds (1–4, 6, and 8, Fig. 1). The structures of known compounds 1 (Hirschfeld et al., 1973) and 3 (Enoki et al., 1982) were established by comparing their physical and spectral data with those in the literature. The new compounds 2, 4, and 6 are acetate derivatives of known alcohols 3 (Enoki et al., 1982), 5 (Enoki et al., 1983), and 7 (Kusumi et al., 1986). Cystoseirol monoacetate 8 represents a new oxidation pattern for this family of hydroazulene diterpenes.

At the outset we recognized a common feature in the mass spectroscopic behavior in five (1–4, 6, and 8, Fig. 1) of the six natural compounds we isolated. Namely, they each gave rise to a major ion (often the base peak) of m/z 159, corresponding to C_{12}H_{13}. This can be accounted for by the events shown in Scheme 1. This analysis suggested that there existed a common structural feature within the hydroazulene skeleton for these five compounds, which localized their structural differences to within the substituents attached to C (6) and/or C (11).

Compound 2 was found to have the formula C_{22}H_{34}O_{3} by mass spectrometry. All twenty-two carbons could be identified in the 13C NMR spectrum. Of the six degrees of unsaturation, implied by the molecular formula of 2, two were...
accounted for as carbon-carbon double bonds (δ = 107.82, 125.22, 140.27, and 152.13) and two more by the presence of acetate (δ = 215.34) and ketone (δ = 171.01) carbonyl groups in the molecule, compound 2 was thus bicyclic. The IR spectrum contained ketone (1710 cm⁻¹) and acetate (1733 cm⁻¹) carbonyl absorption bands. A three-proton singlet at δ 2.04 in the 1H NMR spectrum, resonance at δ 171.14 and 21.98 in the 13C NMR spectrum, and a significant ion at m/z 286 [M + CH₃CO₂H] in the mass spectrum, indicated the presence of an acetate ester in 4. Other spectral similarities between 4 and the known diterpene dictyol F 5 (Enoki et al., 1983) suggested that 4 were a monoacetate of 5. Similar to the differences seen between 2 and 3, the 1H NMR resonance for H (6) was deshielded from δ 3.98 in 5 (Enoki et al., 1983) to δ 5.34 in 4, and the 13C NMR resonance for C (6) from 74.4 in 5 (Enoki et al., 1983) to 79.01 in 4. Thus, 4 were deduced to be dictyol F monoacetate (Fig. 1).

Compound 6 was analyzed for C₂₂H₃₆O₄ by mass spectrometry and ¹³C NMR spectroscopy. Inspection of ¹H NMR and ¹³C NMR data of 6 clearly indicated that the substituents in the carbon skeleton of the bicyclic rings was identical to those present in 4. The major difference was the replacement of resonance associated with the isopropenyl group by a set that could be attributed to the corresponding hydrated tertiary carbinol. Namely, singlets at δ 1.20 and δ 1.15 in the proton spectrum and resonance at δ 23.41 and 26.61 in the
Table I. $^{13}$C-NMR data$^a$ in CDCl$_3$ for compounds 1–4, 6, and 8.

</table>

$^a$ Multiplicity (s, d, t, q) of each carbon is assumed, based upon the observed sign of the DEPT signal (i.e., positive for $\delta$, negative for t, and no signal for s).

carbon spectrum corresponding to diastereotopic methyl groups along with a tertiary carbinol resonance at $\delta$ 73.25 for C(15) suggested the vicinal diol structure present in 6 (Fig. 1). Once again differences for H(6) and C(6) between 6 and known 7 (Kusumi et al., 1986) were consistent with the former being the 6-acetyl analog of the latter. Thus, deshielding of H (6) from $\delta$ 3.94 in 7 [9] to 5.38 in 6 and of C (6), from 74.4 in 7 [9] to 78.58 in 6, along with resonance associated with the C (6) acetoxy group [$\delta$ C = 171.46 and 21.97] led to the assignment of structure 6 as isodictytriol monoacetate (Fig. 1).

Compound 8 was analyzed for C$_{22}$H$_{36}$O$_5$ by mass spectrometry and $^{13}$C NMR spectroscopy. Fragment ion 159 was not present in the mass spectrum of 8 (cf., Scheme 1), suggesting that structural differences resided within the bicyclic moiety. The oxygen-containing functionalities in 8 were identified as one secondary and two tertiary hydroxyl groups [$\delta$ H = 3.30 (dd), $\delta$ C = 78.24, 171.36, and 21.91] as ascertainment from $^1$H- and $^{13}$C NMR spectroscopy. Upon comparing the NMR data for compounds 8 and 6, it was evident that the side chain comprising C (11) to C (16) was identical in both and that the substitution pattern within the five membered ring were different. From $^1$H- and $^{13}$CNMR data of 8 it was surmised that the C (17) methyl group [$\delta$ H = 1.24 (s), $\delta$ C = 17.00 (positive DEPT)] was attached to a quaternary carbon bearing a hydroxyl function [$\delta$ C = 96.6 (no DEPT)]. The alkene within the cyclopentene ring was now di- rather than tri- substituted [$\delta$ H (2) and H (3) = 5.85 (dd, $J$ = 5.7 and 1.8 Hz) and 5.77 (dd, $J$ = 5.7 and 1.7 Hz, $\delta$ C (2) and C (3) = 133.1 and 136.5)]. The presence of a methylcyclopentenol substructure like that assigned here for cystoseirol monoacetate 8 (Fig. 1) has been observed in other hydroazulene diterpenes. One particularly relevant example is dictyotadiol (9), whose relative configuration was deduced by x-ray analysis (Faulkner et al., 1977) and absolute configuration by circular dichroism studies (Arroyo et al., 1991). The same A-ring
Cyclopentenol moiety is also observed in a related hydroazulene diterpene (Wright et al., 1993, König et al., 1993).

The hydroazulene skeleton is typical of diterpenoid metabolites derived from the brown algae of the genus Dictyota. Such structures have also been found in the marine moluscs, Aplysia depilans (Minale and Riccio, 1976). However, the work described here apparently represents the first time such diterpenoid skeletons have been observed in Cystoseiraceae, suggesting a related chemotaxonomy of the brown algae belonging to Cystoseiraceae and Dictyotaceae.

Finally, cytotoxicity assays (Shier, 1983, Abbas et al., 1992) of the total alcohol extract of Cystoseira myrica as well as of the individual compounds after purification (Table II) were carried out in vitro using three proliferating mouse cell lines, a normal fibroblast line NIH3T3 and two virally transformed forms SSVNIH3T3 and KA3IT. All compounds exhibited moderate cytotoxicity on the cancer cell line KA3IT (IC₅₀ = ~ 5 µg/ml) and showed reduced cytotoxicity towards the normal NIH3T3 cells. The total alcohol extract showed more cytotoxic activity against the normal cell line than on the other virally transformed forms.

**Experimental**

*Plant material, apparatus, and methods*

¹H NMR spectra were recorded at 300 or 500 MHz and ¹³C NMR at 75 MHz. Chemical shifts are given in δ (ppm) relative to TMS as internal standard. Overlapped protons in the region of δ 1.2–2.3 are not listed, only discreet resonance from that region of the spectrum is listed. Infrared spectra were determined on thin films cast from CHCl₃, recorded on a Protégé-400 (S.S.P.) spectrophotometer. Electron impact mass spectra were determined at 70 ev on a Kratos MS-25 instrument. Thin layer chromatography was performed on silica gel (kieselgel 60, F254) of 0.25 mm layer thickness. Preparative thin layer chromatography (PTLC) was performed on silica gel plates (20 cm × 20 cm) of 500 µm thicknesses. The alga Cystoseira myrica was collected in June 1998, at El-Zaafarana, near the middle of the Gulf of Suez. A voucher sample was identified by Professor Yahia El-Azab, Department of Botany, Faculty of Science, Mansoura University and deposited at the Pharmacognosy Department, Faculty of Pharmacy, Mansoura University.

**Extraction and isolation**

The alga was air-dried in the shade at room temperature and ground to a powder with a mortar and pestle. This powder (1 kg) was slurred in ethanol (~ 5 l) and allowed to stand at room temperature for several days. Filtration and concentration of the filtrate provided a crude extract that was dissolved in a small amount of methanol, stored at ~0°C overnight, and filtered to remove fats. The filtrate was again evaporated under reduced pressure to afford a dark brown viscous oily residue (~20 g, ~2% of the dry weight of the alga). This residue was chromatographed on a silica gel column using a hexane-ET₂O gradient. Fractions of ~50 ml were collected. The fractions containing a single compound were combined and further purified by preparative TLC to give compounds in the following order:

**Pachydictyol A (1)**

Fractions 5–9 were combined. PTLC using hexane-ETOAc (19:1, v/v) afforded pachydictyol A (30 mg, 0.003% dry wt.). IR (cm⁻¹): 3514 (OH),...
1644 (C = C), EIMS m/z (rel. int.): 288 (25) [M⁺, C₂₀H₃₂O₂⁺], 270 (25) [M⁺−H₂O], 255 (5) [M⁺−CH₃−H₂O], 159 (62) [C₁₂H₁₅⁺]. ¹H NMR (CDCl₃) δ 5.33 [1H, br s, H (3)], 5.12 [1H, t, J = 7.2, H (14)], 4.74 [2H, br s, H (18), H (18’)], 3.92 [1H, br d, J = 7.8, H (6)], 1.80 [3H, s, Me (17)], 1.68 [3H, br s, Me (16)], 1.60 [3H, s, Me (20)], and 0.99 [3H, d, J = 6.0, Me (19)]. ¹³C-NMR (Table I). Spectral properties compare favorably to literature data (Hirschfeld et al., 1973).

**Dictyone acetate (2)**

Fractions 10–16 were combined. PTLC using hexane-EtOAc (9:1, v/v) afforded dictyone acetate 2 as an oil (25 mg, 0.0025% dry wt.). IR (cm⁻¹): 1733 (OAc), 1710 (C = O), 1644 (C = C), EIMS m/z (rel. int.): 286 (14) [M⁺−AcOH, C₂₀H₃₀O⁺], 159 (90) [C₁₂H₁₅⁺], 43 (100) [C₃H₇⁺]. ¹H NMR (CDCl₃) δ 5.33 [1H, br s, H (3)], 5.32 [1H, dd, J = 4.1, 3.6 Hz, H (6)], 4.79 [1H, br s, H (18)], 4.76 [1H, br s, H (18’)], 2.04 [3H, s, Me (Ac)], 1.6 [3H, br s, Me (17)], 1.08 [6H, d, J = 7.0, Me (16), Me (20)], and 0.87 [3H, d, J = 6.8, Me (19)]. ¹³C-NMR (Table I).

**Dictyone (3)**

Fractions 18–25 were combined. PTLC using mixtures of hexane-EtOAc (17:3, v/v) afforded dictyone 3 as a pale yellow oil (20 mg, 0.002% dry wt.). IR (cm⁻¹): 3480 (OH), 1713 (C = O), 1644 (C = C), EIMS m/z (rel. int.): 304 (5) [M⁺, C₂₀H₃₂O₂⁺], 286 (12) [M⁺−H₂O, C₂₀H₃₀O⁺], 159 (45) [C₁₂H₁₅⁺], 145 (12), 107 (30), 71 (40), 43 (100) [C₃H₇⁺]. ¹H NMR (CDCl₃) δ 5.33 [1H, br s, H (3)], 4.06 [1H, dd, J = 8.1, 3.3 Hz, H (6)], 4.74 [2H, br s, H (18), H (18’)], 1.85 [3H, br s, Me (17)], 1.1 [6H, d, J = 6.9, Me (16), Me (20)], and 0.95 [3H, d, J = 6.3, Me (19)]. ¹³C-NMR (Table I). The spectral properties are identical to those reported for 3 (Enoki et al., 1982).

**Dictyol F monoacetate (4)**

Fractions 27–39 were combined. PTLC using hexane-EtOAc (8:2, v/v) afforded dictyol monoacetate 4 as a colorless oil (12 mg, 0.0012% dry wt.). IR (cm⁻¹): 3437 (OH), 1736 (OAc), 1644 (C = C), EIMS m/z (rel. int.): 286 (85) [M⁺−AcOH, C₂₀H₃₀O⁺], 268 (22) [M⁺−AcOH−H₂O], 200 (32), 159 (100) [C₁₂H₁₅⁺], 105 (24), 91 (16), 43 (76) [C₃H₇⁺]. ¹H NMR (CDCl₃) δ 5.34 [1H, dd, J = 8.4, 3.0, H (6)], 5.33 [1H, br s, H (3)], 4.94 [1H, br s, H (20)], 4.83 [1H, br s, H (20’)], 4.79 [1H, br s, H (18)], 4.76 [1H, br s, H (18’)], 4.02 [1H, t, J = 6.1, H (14)], 2.04 [3H, s, Me (Ac)], 1.71 [3H, br s, Me (17)], 1.62 [3H, br s, Me (16)], and 0.83 [3H, d, J = 6.2, Me (19)]. ¹³C-NMR (Table I).

**Isodictytriol monoacetate (6)**

Fractions 72–83 were combined. PTLC using mixtures of hexane-EtOAc (3:1, v/v) afforded isodictytriol monoacetate 6 as a colorless oil (13 mg, 0.0013% dry wt.). IR (cm⁻¹): 3450 (OH), 1736 (OAc), 1640 (C = C), EIMS m/z (rel. int.): 304 (11) [M⁺−AcOH], 286 (5) [M⁺−AcOH−H₂O], 159 (100) [C₁₂H₁₅⁺], 105 (24), 91 (17), 43 (82) [C₃H₇⁺]. ¹H NMR (CDCl₃) δ 5.38 [1H, dd, J = 8.6, 3.7, H (6)], 5.33 [1H, br s, H (3)], 4.79 [1H, br s, H (18)], 4.76 [1H, br s, H (18’)], 3.30 [1H, dd, J = 9.5, 2.0, H (14)], 2.04 [3H, s, Me (Ac)], 1.61 [3H, br s, Me (17)], 1.2 and 1.15 [each 3H, s, Me (16), Me (20)], and 0.89 [3H, d, J = 6.2, Me (19)]. ¹³C-NMR (Table I).

**Cystoseirol monoacetate (8)**

Fractions 85–94 were combined. PTLC using mixtures of hexane-EtOAc (7:3, v/v) afforded cystoseirol monoacetate 8 as a colorless oil (12 mg, 0.0012% dry wt.). IR (cm⁻¹): 3450 (OH), 1732 (OAc), 1640 (C = C), EIMS m/z (rel. int.): 320 (5) [M⁺−AcOH], 302 (18) [M⁺−AcOH−H₂O], 200 (12), 43 (76) [C₃H₇⁺]. ¹H NMR (CDCl₃) δ 5.85 [1H, dd, J = 5.7, 1.8, H (2)], 5.77 [1H, dd, J = 5.7, 1.7, H (3)], 5.48 [1H, dd, J = 9.3, 2.1, H (6)], 4.77 [1H, br s, H (18)], 4.72 [1H, br s, H (18’)], 3.30 [1H, dd, J = 9.6, 2.0, H (14)], 3.0 [1H, br d, J = 9.4, H (1)], 2.04 [3H, s, Me (Ac)], 1.24 [3H, br s, Me (17)], 1.20 and 1.15 [each 3H, s, Me (16), Me (20)], and 0.88 [3H, d, J = 6.2, Me (19)]. ¹³C-NMR (Table I).

**Acetylation of (3)**

A solution of dictyone (5 mg) in a mixture of acetic anhydride (500 µl) and a few drops of pyridine was heated for about 4 h in a water bath and then cooled. It was poured into water and extracted with ether. The ether extract was washed...
Cytotoxicity assays

Cytotoxic assays (Shier, 1983, Abbas et al., 1992) were performed using three proliferating mouse cell lines, a normal fibroblast line NIH3T3 and two virally transformed forms SSVNIH3T3 and KA3IT. Samples of extract or pure compound (5 mg) were dissolved in 62.2 µl of DMSO, and working solutions made by diluting 20 µl of the DMSO solution into 2 ml of sterile medium (Dulbecco’s modified Eagle’s medium, Sigma Chemical Co. St. Louis, MO, USA). Two-fold or 2.5-fold dilutions of the extracts of pure compounds from 200 µg/ml to 0.5 µg/ml were prepared in triplicate in the wells of 96-well culture trays (Falcon Micro Test III, # 3072, Becton Dickinson Labware, Lincoln Park, NJ, USA) in 200 µl of medium containing 5% (v/v) calf serum (Hyclone Laboratories, Logon, Utah, USA). Inoculums of 2 x 103 cells were added to each well in a 100 µl aliquot of 10% calf serum in medium. The 96-well trays of cells were cultured under standard conditions until uninhibited cultures (control) became confluent. The contents of the wells were decanted, and each cell layer washed with a small amount of the medium. The wells were filled with formal saline (3.7% w/v formaldehyde in 0.15 M NaCl), and allowed to stand at room temperature for at least 30 minutes. The trays was washed with tap water, and attached cells stained by adding two drops of 0.5% (w/v) crystal violet solution in 20% (v/v) aqueous methanol added to each well. The trays was washed with tap water, and the IC50 estimated visually as the approximate concentration that causes 50% reduction in the number of stained cells adhering to the bottom of the wells.
