Dedicated to Professor Dr. Dr. h. c. mult. Rudolf Hoppe on the occasion of his 85th birthday

Rb[(Zr₆C)Cl₁₅] was prepared by heating ZrCl₄, Zr powder, RbCl and Al₄C₃ at 850 °C for 21 days. The crystal structure was determined by single crystal X-ray diffraction (space group Pmma, a = 18.484(3), b = 18.962(2), c = 9.708(1) Å, V = 2505.4(6) Å³, and Z = 4). Rb[(Zr₆C)Cl₁₅] crystallises in the Cs[Nb₆Cl₁₅]-type structure. It is built up from two interconnected types of cluster chains, one with linear Zr–Cl–Zr bridges, the other one with bent bridges. The rubidium cations are spread over three different sites within the cluster network which differs significantly from the cation distribution in the comparable potassium and caesium phases. The cation distribution can be rationalised considering the size of the cavities and the Coulombic interactions.

Key words: Zirconium, Halide, Solid State, Cluster, Crystal Structure

Introduction

A prolific cluster chemistry of reduced ternary and quaternary zirconium halides is accessible through methods of high-temperature solid-state chemistry [1 – 5]. Almost all of these phases contain octahedra of zirconium atoms centred by an interstitial atom Z, with Z including H, Be–N, Al–P, and Mn–Ni. These compounds have the general formula A₁⁺[Zr₂ZN(X₁)₁₂Xₙ]⁺, with A⁺ = alkali or alkaline earth metal cation, X = Cl, Br or I, X₁ = inner, edge-bridging halide [6], Xₙ = outer, exo-bonded halide, and 0 ≤ x, n ≤ 6. With different cations, interstitial atoms, and different values of x and n, a large variety of (in most cases) network structures has been established. So far, chlorides and bromides have been found for n = 0 – 6; whereas iodides are limited to n = 0 and 2 [1 – 4].

Phases with n = 3 are a structurally interesting series because all the outer halide atoms in each cluster are shared as (X₃⁻)₆/₂ between neighbouring cluster units. So far, a total of 6 independent cluster network types exist with this type of inter-cluster connectivity. They differ in terms of (–Zr−Cl₃⁻–Zr−) ring sizes, second-nearest neighbour cluster interconnections, and angles at X₃⁻ as well as in the range of sites for any counter cations [7, and refs. cited therein]. Besides the members of the 6 parent structures, further examples exist with mixed halides [8], and also with distorted versions of the more symmetrical archetypes [9].

In this paper we report about a modified synthesis and the single crystal structure of Rb[(Zr₆C)Cl₁₅].

Results and Discussion

The title phase, Rb[(Zr₆C)Cl₁₅], was obtained as a product of the reaction of stoichiometric amounts of ZrCl₄, Zr powder, RbCl, and Al₄C₃ at 850 °C, according to

\[
27 \text{ZrCl}_4 + 9 \text{Zr} + 6 \text{RbCl} + 2 \text{Al}_4\text{C}_3 \rightarrow 6 \text{Rb}[(\text{Zr}_6\text{C})\text{Cl}_{15}] + 8 \text{AlCl}_3
\]

We assume, that the byproduct AlCl₃ serves as flux and improves crystallinity. Rb[(Zr₆C)Cl₁₅] forms black crystals which turn dark red-brown on grinding. The Guinier powder patterns of different reaction products, obtained from a Rb : Zr ratio of 1 : 6 did not show any lines of other cluster phases, but eventually weak lines of non-cluster phases, for example of Rb₂[ZrCl₆] [10]. Rb[(Zr₆C)Cl₁₅] crystallises in the orthorhombic space group Pmma (no. 51) with \(a = 18.484(3), b = 18.962(2), c = 9.708(1) \text{Å}, V = \)

\(R = \frac{\sum ||F_o|| - |F_c||}{\sum |F_o|} = \frac{\sum M w(F_o^2 - F_c^2)^2}{\sum M w(F_o^2)^2}^{1/2}; \ w = 1/\sigma^2(F_o^2) + (0.0440P)^2 + 8.7497P\) where \(P = (F_o^2 + 2F_c^2)/3\). GoF = \(\frac{\sum w(F_o^2 - F_c^2)^2}{m - n}\) where \(m = \) number of observed reflections and \(n = \) number of parameters.

2505.4(6) Å³, and Z = 4. Some important parameters of the data collection and structure refinement are listed in Table 1. The positional and equivalent isotropic displacement parameters are listed in Tables 2 and 3. This phase was identified previously by J.D. Corbett et al. with the aid of Guinier powder diagrams [11]. With a single crystal X-ray structure determination, as presented in this paper, it is possible to determine the distribution of the cations precisely [12].

Within the cluster halides with octahedral hexazirconium units the group with the metal to halide ratio of 6:15 offers the largest variety of different structure types. In all cases three-dimensional networks are found with the Zr clusters connected only by \(X^{2-}\) bridges. So far, six independent structure types have been established [7]. Besides members of the [Nb₆F₁₅] structure [13], realised for example in [[Zr₆Co]Cl₁₅] [14] with only linear Zr–Cl\(^{2-}\)–Zr bridges, three different structure types exist with exclusively bent bridges, namely (1) [Ta₆Cl₁₅] [15] (examples: [[Zr₆N]Cl₁₅] and Na₆[[Zr₆N]Cl₁₅] [16]) (2) Rb₅[[Zr₆Be]Br₁₅] [17] (example besides the parent structure: Cs₂[[Zr₆Z]Br₁₅] (Z = B, C) [18]), and (3) Cs[[ZrC]]·Cs[[ZrMn]Cl₁₅] [19] (examples besides the parent structure: Cs[[ZrCl₅]]·Cs₂[[Zr₆Be]Cl₁₅] and Cs[[ZrC]]·Cs₂[[Zr₆Be]Cl₁₅]₄₄₁₄ [8]). The two remaining independent structure types contain both linear and bent Zr–Cl\(^{2-}\)–Zr bridges. These are the K₂[[Zr₆B]Cl₁₅] [9] (for example: K₂[[Zr₆Be]Cl₁₅]) and the Cs[[Nb₆Cl₁₅]] structure types [20] (examples: K[[Zr₆C]Cl₁₅] [11], Cs[[Zr₆C]Cl₁₅] [11, 12], CsK[[Zr₆B]Cl₁₅] [11], and K[[Zr₆N]Cl₁₅] [21]). The title phase belongs to the latter structure type.

In the Cs[[Nb₆Cl₁₅]] structure two different types of cluster chains exist. One is a linear chain, which runs parallel to the crystallographic c axis. The other one runs along the a axis and contains bent Zr–Cl\(^{2-}\)–Zr bridges, thereby forming zigzag chains. The two symmetry-independent cluster units, from which these two chains originate, are shown in Fig. 1. Fig. 2 shows the arrangement of the two cluster chains in the unit cell. The Zr₆ octahedra of the linear chains are tetragonally compressed along the c axis by 0.05 Å with an average Zr–C distance of 2.241 Å along, and 2.291 Å perpendicular to the chain direction. The metal octahedra of the zigzag chains are also tetragonally compressed by about 0.03 Å in the chain direction.
with Zr–C distances of 2.2546(6) and 2.2873(4) Å. The Zr–Cl $^{\text{eq}}$–Zr-angle of the zigzag chains measures 137.19°. The three-dimensional cluster network is formed by additional Cl$^{\text{eq}}$–Zr bridges between the two different chain types with Zr–Cl$^{\text{eq}}$–Zr-angles of 131.34°. Within this cluster network cavities exist, in which the alkali cations are accommodated. As can be seen from the data in Table 4, which compares the structural data of the title phase with those of the homeotypic compounds K[(Zr$_6$C)Cl$_{15}$] [11] and Cs[(Zr$_6$C)Cl$_{15}$] [11, 12], the Zr1–Cl1–Zr3 and Zr2–Cl3–Zr2$^{\#}$ angles (symmetry operation #: $-x+3/2, 1-y, z$) are expanded with increasing cation size. Thereby, the cavities, which host the cations within the cluster network, are expanded and adapted to the size of cation. From the other members of this structure type it is known already [11] that three different network cavities are used by the cations. These are the Wyckoff sites 4k, 2f, and 2c of the space group $Pmma$. Regarding the question what type of cation takes which site, the size and the bonding capabilities of the cation are the most important parameters. Whereas in K[(Zr$_6$C)Cl$_{15}$] the

* Symmetry code #: −x + 3/2, −y + 1, z.

4k site is exclusively occupied by the K cation [11], in the Rb and Cs salts the cations also use the 2f and 2c sites. When these two additional sites are occupied, an interesting interplay takes place between the size requirements of the cations and the Coulomb interactions between the cations and the surrounding halide ions. This interplay can be illustrated by a comparison of the structural data of the K, Rb, and Cs cluster salts, which are compiled in Tables 4 and 5.

As already mentioned above, the cation in K[(Zr₆C)Cl₁₅] occupies exclusively the Wyckoff site 4k with a coordination polyhedron consisting of 10 Cl atoms forming a distorted, doubly capped cube. The average Cl–K distance measures $d = 3.419$ Å, a value which compares well with the sum of the ionic radii (3.40 Å [21], Shannon values). Changing to the heavier rubidium cation the 4k cavity size increases slightly. It is occupied by the Rb3 cation, which has a coordina-

Fig. 3. The halide environment of the Rb3 cation, located on the Wyckoff site 4k (displacement ellipsoids at the 50% probability level).

Fig. 4. The halide environment of the Rb1 cation, located on the Wyckoff site 2f (displacement ellipsoids at the 50% probability level).

Fig. 5. The halide environment of the Rb2 cation, located on the Wyckoff site 2c (displacement ellipsoids at the 50% probability level).
large enough for the rubidium cation. Interestingly, in the caesium phase the average Cs–Cl distance is not larger than in the Rb phase, but smaller by 0.023 Å. Comparison of the average Cs–Cl distance (3.408 Å) with the sum of the ionic radii of ten-fold coordinated Cs⁺ (3.62 Å) shows that the site 4k is too small to accommodate larger amounts of Cs. Therefore, only 5% of the total caesium content of this phase is found on the 4k site. The coordination environment of the Rb1 cation on the site 2f is shown in Fig. 4, that of Rb2 on the Wyckoff site 2c in Fig. 5. Both cations are surrounded by 8 chlorine atoms. In Cs[(Zr6C)Cl15] the 2f site is fully occupied. From the comparison of the sum of the ionic (Shannon) radii for a caesium cation (3.62 Å) shows, that there is no size restriction. Another possible factor that can influence the amount of site occupation, is the coordination geometry of the Rb1 cation on the site 2f. It is slightly smaller than the PMF for the 2f site, which calculates to 0.57163. These numbers correlate nicely with the observed occupation of these two cation sites.

**Experimental Section**

All manipulations were carried out in an argon filled glove box or under high vacuum because of the moisture and air sensitivity of the starting materials and the products. Zr was obtained by a process of hydrogenation, grinding and subsequent dehydrogenation of reactor grade Zr pieces [23, 24].

Al₄C₃ powder (ABCR, > 99 %) was degassed at 800 °C under high vacuum prior to use. Neither X-ray powder diagrams, nor the colour of this material indicated the presence of nitrogen containing Al phases [25]. ZrCl₄ (Aldrich, < 50 ppm Hf, 99.5 %) and RbCl (Alfa Aesar, > 99.9 %) were purified by sublimation under high vacuum.

**Synthesis of Rb[(Zr₆C)Cl₁₅]**

Crystals of the title compound were prepared by sealing 233.0 mg (1,000 mmol) of ZrCl₄, 30.4 mg (0.373 mmol) of Zr, 62.7 mg (0.519 mmol) of RbCl and 10.7 mg (0.074 mmol) of Al₄C₃ in a welded niobium ampoule. The vessel was sealed into an evacuated silica ampoule to protect it from oxidation during the reaction. The silica ampoule was placed in a tube furnace. The temperature of the furnace was first raised to 350, and then to 500 and 750 °C. After each increase the temperature was held for at least 24 h. In a final step the temperature was raised to 850 °C and held for 21 d. Subsequently, the reaction container was quenched under water. The product was obtained in form of black crystals.

**X-Ray structure determination**

Black single crystals of the title compound were selected under a microscope (15× magnification) inside an argon-filled glove box and sealed into thin-walled glass capillaries. X-Ray intensity data were collected at r.t. with a Siemens

* $R = \sum_{\text{ion}, \text{M}} X$; $X =$ percentage of the overall halide contents; distances to the 2c position; b the refinement was carried out with a split model with an occupied 4i position instead of the 2c position.
P4 four-circle diffractometer with graphite-monochromated MoKα radiation (λ = 0.71073 Å).

All processing of the data was carried out using XSCANS 2.0. The structure was solved in the orthorhombic space group Pnma (no. 51) using Direct Methods and refined by full-matrix least-squares methods on F² using the SHELX-97 program package [26]. The occupational factors of all Rb positions were refined unconstrained.

Further details about the crystal structure investigation may be obtained from Fachinformationszentrum Karlsruhe, 76344 Eggenstein-Leopoldshafen, Germany (fax: +49-7247-808-666; e-mail: crysdata@fiz-karlsruhe.de, http://www.fiz-informationsdienste.de/en/DB/icsd/depot_anforderung.html) by quoting the deposition number CSD-417754.

Acknowledgements

Financial support provided by the Deutsche Forschungsgemeinschaft and the State of North Rhine-Westphalia through a Benningsen-Forerder award for M. K. is gratefully acknowledged. We are also grateful to Prof. Dr. G. Henkel (University of Paderborn) for all his support and to Jan Miller for proof reading.
