Introduction

Ionic liquids have become highly relevant to chemical synthesis, including the preparation of compounds and materials such as metal-organic coordination complexes, metal-organic frameworks, zeolites, or nanoparticles [1–4]. Recently, imidazolium-based ionic liquids have received specific interest in inorganic compounds [5–7]. Quite often unique coordinative complexes and coordination polymers could already be obtained [1–3, 5–7]. Depending on the properties of the counterion, several coordination complexes and coordination polymers could already be obtained [1–3, 5–7]. Quite often unique coordinative bonding and/or structural building units are observed for compounds prepared in ionic liquids. This is due to the non-coordinating properties of some ionic liquids, favoring a coordination of ligands that is typically not observed in the presence of conventional, coordinating solvents (e.g., alcohols, amines).

Coordination complexes with the – in principle – weakly coordinating [OTf]− or [NTf2]− anions were recently presented by Mudring and coworkers. The octanuclear europium cluster [BMPyr]_{6}[Eu_4(μ_4-O)(μ_2-OH)]_{12}(μ_2-OTf)]_{14}(μ_1-Ti)(HOTf)]_{15} was synthesized in the ionic liquid [BMPyr][OTf] (BMPyr: butylimethylpyrrolidinium, OTf: trifluoromethanesulfonate) [8]. This polynuclear complex is surrounded by a total of sixteen triflate anions, of which fourteen coordinate as µ₂-ligands. As expected, [OTf]− is a more strongly coordinating ligand. For example, [Ni_5(cyclam)]^{2+} cationic complex (cyclam: 1,4,8,11-tetraazacyclotetradecane) exhibited a chain-like [Ni_5(cyclam)]^{2+} structure. This is due to the non-coordinating properties of some ionic liquids, favoring a coordination of ligands that is typically not observed in the presence of conventional, coordinating solvents (e.g., alcohols, amines).

only as a non-coordinating anion [10]. There are only few reports on complexes comprising [OTI]<sup>−</sup> or [NTI]<sup>−</sup> as a bidentate bridging ligand. Thus, [MPPyr][Ba(NTI)<sub>2</sub>]<sub>3</sub> contains infinite 1/2[Ba(NTI)<sub>2</sub>]<sup>−</sup> chains [9]. Moreover, alkali and alkaline earth metal triflates as well as silver triflate are known to exhibit [OTI]<sup>−</sup> as a bridging ligand in layers [11–14].

As part of our studies regarding the potential of ionic liquids in inorganic synthesis [15, 16], we obtained the new coordination compounds [BMIm][Fe(OTf)<sub>3</sub>], [BMIm][Mn(OTf)<sub>3</sub>] and [BMIm][Li(OTf)<sub>2</sub>]. The title compounds were prepared by simple heating of FeCl<sub>2</sub>, MnCl<sub>2</sub> and LiCl in [BMIm][OTf] as the ionic liquids (BMIm: 1-butyl-3-methylimidazolium). Well-shaped crystals of [BMIm][M(OTf)<sub>3</sub>] (M: Fe<sup>II</sup>, Mn<sup>II</sup>) were alternatively obtained by mild oxidation of Fe(CO)<sub>5</sub> or Mn<sub>2</sub>(CO)<sub>10</sub> with GeI<sub>4</sub> in the respective ionic liquid. All compounds contain infinite 1/2[M(OTf)<sub>3</sub>] (M: Fe, Mn) or 1/4[M(OTf)<sub>2</sub>] chains (M: Li), in which iron/manganese and lithium are coordinated by six and four [OTI]<sup>−</sup> anions, respectively, which serve as bidentate bridging ligands.

**Results and Discussion**

For optimal crystal growth, the compounds [BMIm][M(OTf)<sub>3</sub>] (M: Fe, Mn) were prepared by mild oxidation of Fe(CO)<sub>5</sub> or Mn<sub>2</sub>(CO)<sub>10</sub> with GeI<sub>4</sub> in [BMIm][OTf] as the ionic liquid. During the reaction, Fe<sup>2+</sup>/Mn<sup>2+</sup> (in Fe(CO)<sub>5</sub>/Mn<sub>2</sub>(CO)<sub>10</sub>) were oxidized according to the following equation to Fe<sup>3+</sup>/Mn<sup>3+</sup> ([BMIm][M<sup>3+</sup>(OTf)<sub>3</sub>], [BMIm][Mn<sup>3+</sup>(OTf)<sub>3</sub>]) whereas Ge<sup>4+</sup>/Ge<sup>0</sup> was reduced to Ge<sup>0</sup>:</n
debug

\[ \text{2Fe(CO)}_5 + \text{GeI}_4 \rightarrow \text{2Fe}^{2+} + \text{Ge}^0 + 4\text{I}^- + 10\text{CO} \]
\[ \text{Mn}_2(\text{CO})_{10} + \text{GeI}_4 \rightarrow 2\text{Mn}^{2+} + \text{Ge}^0 + 4\text{I}^- + 10\text{CO} \]

In this convenient redox reaction, the formation of Fe<sup>3+</sup>/Mn<sup>3+</sup> and the crystallization of [BMIm][M<sup>3+</sup>(OTf)<sub>3</sub>] are obviously retarded, which favors crystal growth. The synthesis resulted in moisture-sensitive colorless and well-shaped needles of the title compounds. Crystals of [BMIm][Li(OTf)<sub>2</sub>] were synthesized by direct heating of dried LiCl in [BMIm][OTf] and led also to the formation of moisture-sensitive, colorless and well-shaped needles. Interestingly, simple heating of FeCl<sub>2</sub> and MnCl<sub>2</sub> in [BMIm][OTf] – analogous to the reaction of LiCl in [BMIm][OTf] – only led to small, irregularly formed and conjoined crystals of [BMIm][M(OTf)<sub>3</sub>] (M: Fe, Mn).

The chemical composition of all title compounds was verified, aside from X-ray structure analysis, by EDX, FT-IR and DTA-TG. Thus, EDX analysis evidences the presence of iron and manganese as well as sulfur and fluorine for [BMIm][M(OTf)<sub>3</sub>] (M: Fe, Mn). The measured metal-to-sulfur ratio of 1 : 2.8 ([BMIm][Fe(OTf)<sub>3</sub>]) and 1 : 2.4 ([BMIm][M(OTf)<sub>3</sub>]) matches within the significance of measurement with the expected ratio (1 : 3). For [BMIm][Li(OTf)<sub>2</sub>], with lithium as a light element, EDX analyses is not meaningful. The presence of lithium was therefore verified via flame spectroscopy, indicating the red emission and the characteristic emission lines of lithium. FT-IR spectroscopy evidences the presence of the cation ([BMIm]<sup>+</sup>) and the anion ([OTI]<sup>−</sup>) (Fig. 1). Due to coordination of the oxygen atoms to the metal center, the S–O valence vibrations between 1300 and 1100 cm<sup>−1</sup> are more expanded and slightly shifted to higher wavenumbers compared to the pure ionic liquid. According to TG analysis, all compounds show a one-step decomposition at temperatures of 320–350°C. In addition, DTA exhibits weak endothermal peaks at 100–150°C, indicating the melting points of the compounds (Table 1).

X-Ray structure analyses based on single crystals revealed [BMIm][M(OTf)<sub>3</sub>] (M: Fe, Mn) to crystallize with monoclinic lattice symmetry and [BMIm][Li(OTf)<sub>2</sub>] to crystallize in the triclinic space group P1 (Table 2, Fig. 2). The compounds are composed of infinite 1/2[M(OTf)<sub>3</sub>] chains. Herein, the metal atoms are

interlinked by six \((M: \text{Fe, Mn})\) and four \((M: \text{Li})\) \([\text{OTf}]^−\) anions that act as bidentate bridging ligands (Figs. 3, 4). The infinite chains are oriented parallel to each other along the crystallographic \(b\) ([BMIm][M(OTf)₃] \((M: \text{Fe, Mn})\)) and \(c\) axis ([BMIm][Li(OTf)₂]). In all cases, the cations [BMIm]⁺ are located between the one-dimensional \(M(\text{OTf})x\) chains. In [BMIm][M(OTf)₃] \((M: \text{Fe, Mn})\), each metal center is coordinated distorted octahedrally by six oxygen atoms from six different \([\text{OTf}]^−\) anions. The O–M–O angles range from 83.2(1) to 93.3(1)° for [BMIm][Fe(OTf)₃] and from 83.6(1)° to 95.9(2)° for [BMIm][Mn(OTf)₃]. The trans-angles deviate slightly from 180° with 174.9(1)–178.2(1)° for [BMIm][Fe(OTf)₃] and 174.6(1)–178.2(1)° for [BMIm][Mn(OTf)₃]. In [BMIm][Li(OTf)₂], the lithium atoms are coordinated in distorted tetrahedra. Compared to the tetrahedral reference angle of 109.5°, the angles are alternately widened and narrowed (104.9(2)–115.5(2)°).

The parallel \(1\_\infty\)[M(OTf)₃] chains of all title compounds are interconnected via C–H···F hydrogen bonds between H atoms of the cations and fluorine atoms of the triflate anions. In the case of the Mn compound, three short hydrogen bonds are observed with distances around 263 pm (F₃···H⁹a: 262.6(1); F₆···H₁₁a 262.7(1), F₃···H₁₁C: 264.0(1) pm), one with 269.8(1) pm (F₇···H₁₀B), and the longest ones with 274.6(1) (F₄···H₇B) and 287.1(1) pm (F₄···H₁₀A). The situation is similar for [BMIm][Fe(OTf)₃], however, the shortest hydrogen bond with 257.1(1) pm (F₃···H₁₁A) is even slightly shorter. For [BMIm][Li(OTf)₂], there are three hydrogen bonds of very different lengths. With 256.8(1), 263.0(1) and 263.3(1) pm, the shortest of these distances are observed for the Fe/Mn compounds. According to liter-
nature, all these values are in the range of moderate hydrogen bonding [18, 19].

The metal-to-metal distances in the chain-like [BMIm][M(OTf)$_3$] compounds are 463.3(1) (Fe···Fe) and 470.1(1) pm (Mn···Mn) (Figs. 3, 4), significantly exceeding the doubled covalent radii of 304 pm (Fe$^{3+}$) and 322 pm (Mn$^{2+}$) [17]. Consequently, any attractive metal-metal interaction can be excluded. The $c$ axis in the manganese compound is slightly elongated as compared to the iron compound due to the larger radius of the Mn$^{2+}$ cation. In view of the small size of Li$^+$ (59 pm) and due to its preferred tetrahedral coordination, the Li···Li distances in [BMIm][Li(OTf)$_2$] of 442.4(1) pm are much smaller as compared to [BMIm][M(OTf)$_3$] ($M$: Fe, Mn). Although the metal-to-metal distances are too long for any bonding interaction, for [BMIm][M(OTf)$_3$] ($M$: Fe, Mn) magnetic coupling might occur between the paramagnetic metal centers. To study such interactions, magnetic measurements of [BMIm][Fe(OTf)$_3$] were performed with a SQUID magnetometer (Fig. 5). Curie-Weiss behavior and strong antiferromagnetic coupling were observed, the experimental room temperature $\chi T$ value being 3.04 cm$^3$ K mol$^{-1}$. These data are consistent with what is expected for high-spin Fe$^{3+}$ ions ($d^6$, $S = 2$, $C = 3.0$ cm$^3$ K mol$^{-1}$). Since the preparation of phase-pure [BMIm][Mn(OTf)$_3$] turned out to be much more difficult than for the Fe compound, and since analogous antiferromagnetic coupling can be assumed for Mn$^{2+}$ as well, magnetic measurements of [BMIm][Mn(OTf)$_3$] were not performed.

Conclusion

Ionic-liquid-based syntheses resulted in [BMIm][Fe(OTf)$_3$], [BMIm][Mn(OTf)$_3$] and [BMIm][Li(OTf)$_2$] as new coordination compounds that contain infinite [M(OTf)$_3$]$^-$ chains. Their bidentate bridging coordination by weakly coordinating [OTf]$^-$

anions is still rare. Although [BMIm][Fe(OTf)3] and [BMIm][Mn(OTf)3] can be obtained by simple heating of FeCl2 and MnCl2 in [BMIm][OTf], a significantly improved crystal quality is achieved by applying the mild oxidation of Fe(CO)5/Mn(OTf)2 by GeI4 in the ionic liquids. The decelerated formation of [BMIm][Fe(OTf)3] and [BMIm][Mn(OTf)3] favors a controlled crystal growth in the highly viscous ionic liquid. Crystal structure and phase composition of all title compounds were validated by crystal structure analysis, EDX, FT-IR and DTA-TG. DTA indicates a melting of the title compounds in the range 98 – 150 °C and the thermal decomposition at 300 – 350 °C. Magnetic measurements show Curie-Weiss behavior with strong antiferromagnetic coupling for [BMIm][Fe(OTf)3].

Fig. 5 (color online). Magnetic properties of [BMIm][Fe(OTf)3].
General considerations

All sample handling was carried out under standard Schlenk and argon glove-box techniques. Reactions took place in argon-filled and sealed glass ampoules that were dried under reduced pressure (1 × 10⁻³ mbar) at 300°C before use. The commercially available starting materials FeCl₂ (98%, Sigma Aldrich), MnCl₂ (> 99%, Sigma Aldrich) and LiCl (> 99%, Aldrich) were dried overnight by heating to 150°C in vacuum; Fe(CO)₅ (99.999%, Sigma Aldrich), Mn₂(CO)₁₀ (98%, Sigma Aldrich) and GeI₄ (99.99% Sigma Aldrich) were used as received. The ionic liquid [BMIm][OTf] (Merck, 99%) was dried under vacuum for 48 h before use.

Syntheses

[BMIm][Fe(OTf)₃]

FeCl₂ (100 mg) was dissolved in the ionic liquid [BMIm][OTf] (1 mL) and heated in a sealed glass ampoule at 130°C for 4 d. After cooling to room temperature with a rate of 1 K h⁻¹, very small and conjoined colorless crystals of limited quality were obtained. Well-shaped transparent crystals were alternatively obtained by reacting Fe(CO)₅ (0.02 mL, 0.15 mmol) and GeI₄ (100 mg, 0.17 mmol) in the ionic liquid [BMIm][OTf]. This solution was left in a sealed glass ampoule at 130°C for 10 days. After cooling to room temperature with a rate of 1 K h⁻¹, well-shaped colorless, transparent crystals were obtained in large quantities (about 70% yield according to the total amount of iron). In addition, a dark-grey residue was observed that according to X-ray diffraction analysis turned out to be elemental germanium. Crystals of the title compound were separated manually for crystal structure analysis.

[BMIm][Mn(OTf)₃]

[BMIm][Mn(OTf)₃] was synthesized similarly. Instead of FeCl₂, MnCl₂ was used. For high-quality crystals, Mn₂(CO)₁₀ (48 mg, 0.12 mmol) was reacted with GeI₄ (100 mg, 0.17 mmol) in 1 mL ionic liquid. The compound crystallizes as colorless, transparent needles, but, in contrast to [BMIm][Fe(OTf)₃], with limited yield of only about 10%.

Analytical tools

Crystal structure determination

Single-crystal structure analyses of all title compounds were performed on an IPDS II diffractometer (Stoe, Darmstadt) using graphite-monochromatized MoKα radiation (λ = 0.71073 nm). Suitable crystals were isolated in inert oil and mounted on a glass capillary. Structure solution and refinement were conducted based on the program package SHELX [20]. The results are listed in Table 2. A numerical absorption correction was applied; hydrogen atoms were geometrically constructed [20]. All illustrations were created with DIAMOND [21].

CCDC 900307 ([BMIm][Fe(OTf)₃]), CCDC 900309 ([BMIm][Mn(OTf)₃]), and CCDC 900308 ([BMIm][Li(OTf)₂]) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Energy-dispersive X-ray analysis

EDX was carried out using an AMETEC EDAX device mounted on a Zeiss SEM Supra 35 VP scanning electron microscope. For measurement, single crystals were fixed with conductive carbon pads on aluminum sample holders.

Fourier-transformed infrared spectroscopy

FT-IR spectra were recorded on a Bruker Vertex 70 FT-IR spectrometer; the samples were measured as pellets in KBr. For this purpose, 300 mg of dried KBr and 2 mg of the sample were carefully pestled together and pressed to a thin pellet.

Differential thermal analysis/thermogravimetry

DTA/TG were performed with a Netzsch STA 409C instrument applying α-Al₂O₃ as a crucible material and reference sample. The samples were heated under N₂ flow to 800°C with a heating rate of 5 K min⁻¹.

Magnetic measurements

Magnetic measurements were performed with a Quantum Design MPMS-XL SQUID magnetometer using samples composed of single crystals at temperatures between 1.8 and 300 K with magnetic fields up to 7 T. The susceptibility was measured with 1000 Hz and 3 Oe oscillating alternating magnetic field (1 Oe = 79.6 A m⁻¹). Corrections for sample holder and diamagnetic contribution were applied.
