1,2,5,6,9,10-Hexaalkoxyhexahelicenes $\mathbf{3}$ represent [3]star compounds with a helical core. A multistep synthetic concept for $\mathbf{3}$ is discussed, in which the final step $\mathbf{1 6} \rightarrow \mathbf{3}$ is a twofold oxidative photocyclization. The linearly conjugated compounds $\mathbf{1 6}$ contain stilbene and vinylnaphthalene units.

Key words: Helicenes, Photocyclization, Wittig-Horner Reaction, Siegrist Reaction

## Introduction

[3]Star compounds, which consist of conjugated aromatic cores and three, six or nine alkoxy groups, represent interesting structures for materials science [1]. 2,3,6,7,10,11-Hexaalkoxytriphenylenes (1) are prominent examples (Fig. 1). From their first preparations [2,3] till our days [4-9], a large variety of compounds 1 have been thoroughly studied. Much less is known about $1,2,5,6,9,10$-hexaalkoxycoronenes (2) $[10,11]$, and nothing is known about 1,2,5,6,9,10hexaalkoxyhexahelicenes (3). In contrast to $\mathbf{1}$ and 2, compound 3 has a non-planar, chiral polycyclic core. Many mesophases are known for compounds 1, some for systems 2. This arises the question: Do chiral thermotropic liquid crystalline phases (LC) exist for 3? Due to the lack of symmetry, the usual synthesis of hexahelicenes on the basis of 2,7-distyrylnaphthalenes [12], is not useful
in this case. We conceived a multi-step procedure, which starts from benzene and naphthalene derivatives.

## Results and Discussion

Scheme 1 summarizes the preparation of the 2-\{2-[4-(2-phenylvinyl)phenyl]vinyl\}naphthalenes 16a, b, which were chosen as precursors for the desired hexahelicenes 3.

3-Methylbenzene-1,2-diol (4) was alkylated twice under phase transfer conditions [13, 14]. We used long alkyl chains to get high solubilities throughout the whole reaction sequence. The obtained 3-methyl-1,2-dialkoxybenzenes 6a, b were subjected to a Bouveault formylation to $\mathbf{7 a}, \mathbf{b}$. The formylation was neither regioselective nor chemoselective; the $\mathrm{CH}_{3}$ group was also attacked by DMF $[15,16]$. Consequently the yields of $\mathbf{7 a}, \mathbf{b}$ were low. In a second reaction se-

quence, $\mathbf{6 a}, \mathbf{b}$ were transformed to the phosphonates 9a, b via the bromides 8a, b [14]. Wittig-Horner reactions $\mathbf{7 a} \mathbf{+ 9 a}$ and $\mathbf{7 b + 9 b}$ gave the $(E)$-configured stilbenes 10a and 10b, respectively.

The naphthalene moiety of $\mathbf{1 6 a}, \mathbf{b}$ was synthesized on the basis of the ester $\mathbf{1 1}$ [17, 18], which was alkylated with the bromoalkanes 5a, b to obtain 12a, b. Reduction with $\mathrm{LiAlH}_{4}$ yielded the alcohols 13a,

b, which were gently oxidized by 2,3-dicyano-5,6-dichloro-1,4-benzoquinone (DDQ) to the aldehydes 14a, b. The reaction with aniline gave then the Schiff bases $\mathbf{1 5 a}, \mathbf{b}$. In contrast to the left branch of the synthetic Scheme 1, all yields in the right branch are very high. The four steps from 11 to 15a have for example an overall yield of $88 \times 0.94 \times 0.95 \times 100=78.6 \%$. Siegrist reactions [19] of $\mathbf{1 0 a}+\mathbf{1 5 a}$ and $\mathbf{1 0 b}+\mathbf{1 5 b}$ gave then 16a and 16b, respectively. The stereoselectivity
in favor of the ( $E$ )-configuration is so high that the ( $Z$ )isomers could not be detected in the NMR spectra of the crude reaction products $\mathbf{1 6 a}, \mathbf{b}$ [20].

Irradiation of $(E, E)$ - $\mathbf{1 6 a}, \mathbf{b}$ led to the formation of the two possible $(E, Z)$-isomers and the $(Z, Z)$-isomer, which subsequently underwent cyclization and oxidation to $\mathbf{1 7 a}, \mathbf{b}$ and/or 18a, b (Scheme 2). The second photocyclization and oxidation gave 3a and 3b, respectively, in good overall yields. In principle, an

unsubstituted system 16 would have four cyclization modes, which can lead to four different condensed benzenoid aromatics; however, the alkoxy groups in 16a, b block three cyclization routes, so that only the route $\mathbf{1 6 a}, \mathbf{b} \rightarrow \mathbf{3 a}, \mathbf{b}$ remains. Iodine served as oxidant and methyloxirane as scavenger for the generated hydrogen iodide [21]. At the stage of the not isolated intermediates $\mathbf{1 7}$ and/or 18, photoisomerizations have to be assumed.

The racemates 3a and 3b are pale-yellow oils which solidify below $-20^{\circ} \mathrm{C}$. Both compounds exhibit very different DSC curves (Fig. 2); however, the formation of thermotropic mesophases could be excluded by polarization microscopy. Liquid crystals are very rare in the series of hexahelicenes [22, 23]. The broad peak in the heating and cooling curve of $\mathbf{3 a}$ is unusual. It can be possibly due to a superposition of several closelying phase transitions in the solid state. Impurities and

The hexahelicenes $\mathbf{3 a}, \mathbf{b}$ belong to the point group $C_{1}$, they are chiral. Consequently they show ten aromatic CH signals, ten $C_{q}$ and six $C_{q} \mathrm{O}$ signals in the ${ }^{13} \mathrm{C}$ NMR spectra. Most characteristic are their ${ }^{1} \mathrm{H}$ NMR signals (Table 1). The aromatic protons give three AB and one $A B C D$ spin patterns. The signals at highest field in the aromatic region were found for $11-\mathrm{H}$ at $\delta=6.33$ and 6.32 ppm , respectively. The overlap of the terminal benzene rings and the high electron density, induced by the $10-$ OR groups, are the reason for the resonance at unusually high field.

## Conclusion

The hexahelicenes $\mathbf{3 a}$ and $\mathbf{3 b}$ are the first examples of [3]star compounds with a helical core consisting of a hexahelicene structure. Their preparation in a multistep synthesis was based on the twofold oxidative photocyclization of the linearly conjugated 2-(4-styrylstyryl)naphthalenes 16a and 16b (Schemes 1 and 2).

## Experimental Section

NMR spectra were recorded on a Bruker AM 400 spectrometer operating at 400 MHz for ${ }^{1} \mathrm{H}$ and 100 MHz for ${ }^{13} \mathrm{C}$.

FD MS ( 5 kV ) and EI MS ( 70 eV ) measurements were performed with a Finnigan MAT 95 spectrometer. UV/Vis spectra were obtained with a Zeiss MCS 320/340 diode array spectrometer. Melting points were taken on a Büchi apparatus and are uncorrected. A Perkin-Elmer DSC 7 instrument served for the differential scanning calorimetry (DSC). Polarization microscopy was performed with a Leitz Ortholux II microscope. Elemental analyses were determined in the microanalytical laboratory of the Chemistry Department of the University of Mainz.
The synthetic sequence $\mathbf{4} \rightarrow \mathbf{6 a}, \mathbf{b} \rightarrow \mathbf{8 a}, \mathbf{b} \rightarrow \mathbf{9 a}, \mathbf{b}$ is described elsewhere [14].

It was not necessary to isolate the intermediate bromo compounds 8a, b. However, the oily compound 2,3bis(hexyloxy)benzylbromide (8a) was checked for its purity by NMR control. - ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=0.88-1.01$ ( $\mathrm{m}, 6 \mathrm{H}, \mathrm{CH}_{3}$ ), 1.25-1.45 (m, 8 H, CH $)$ ), $1.45-1.61$ (m, $\left.4 \mathrm{H}, \mathrm{CH}_{2}\right), 1.75-1.94\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{CH}_{2}\right), 3.95\left(\mathrm{t},{ }^{3} \mathrm{~J}=6.3 \mathrm{~Hz}\right.$, $2 \mathrm{H}, \mathrm{OCH}_{2}$ ), $4.13\left(\mathrm{t},{ }^{3} \mathrm{~J}=6.6 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{OCH}_{2}\right), 6.83(\mathrm{dd}$, $\left.{ }^{3} J=6.8 \mathrm{~Hz},{ }^{4} J=2.9 \mathrm{~Hz}, 1 \mathrm{H}, 4-\mathrm{H}\right), 6.89-7.02(\mathrm{~m}, 2 \mathrm{H}, 5-$ $\mathrm{H}, 6-\mathrm{H}) .-{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta=13.9,14.0\left(\mathrm{CH}_{3}\right), 22.5$, $22.6,25.7,25.8,29.7,30.3,31.5,31.7\left(\mathrm{CH}_{2}\right), 28.3\left(\mathrm{CH}_{2} \mathrm{Br}\right)$, 113.7 (C-4), 122.3, 123.7 (C-5, C-6), 131.9 (C-1), 146.7, 152.3 (C-2, C-3). ## Bouveault formylation of $\mathbf{6} \boldsymbol{a}, \boldsymbol{b}$ to $7 \boldsymbol{a}, \boldsymbol{b}$

Benzene derivative 6a, b $(22.0 \mathrm{mmol})$ and $N, N^{\prime}-$ tetramethylethylendiamine (TMEDA, $3.0 \mathrm{~mL}, 33.0 \mathrm{mmol}$ ) were dissolved in 100 mL of dry and deoxygenated diethyl ether. A 2.7 M solution of $n$-butyllithium in hexane $(21.0 \mathrm{~mL}, 33.0 \mathrm{mmol})$ was added and the mixture stirred for 3 h at ambient temperature, before dimethylformamide (DMF, $2.3 \mathrm{~mL}, 33.0 \mathrm{mmol}$ ) was added. After a further hour at room temperature, first $\mathrm{H}_{2} \mathrm{O}(10 \mathrm{~mL})$ and then 2 M HCl $(10 \mathrm{~mL})$ were slowly dropped into the mixture. The organic layer and the extract of the water layer ( 50 mL diethyl ether) were unified, neutralized $\left(\mathrm{NaHCO}_{3}\right)$, dried $\left(\mathrm{MgSO}_{4}\right)$ and evaporated. The residue was purified by column filtration $\left(5 \times 40 \mathrm{~cm} \mathrm{SiO} \mathrm{O}_{2}\right.$, toluene or $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ).

## Preparation of the phenanthro[3,4-c]phenanthrenes 3a, b

A solution of $0.7 \mathrm{mmol} \mathbf{1 6 a}, \mathbf{b}$ and $0.35 \mathrm{~g}(1.4 \mathrm{mmol}) \mathrm{I}_{2}$ in 2 L of dry benzene was purged by a stream of oxygenfree nitrogen for 0.5 h . Methyloxirane ( $4.9 \mathrm{~mL}, 70 \mathrm{mmol}$ ) was added and the mixture irradiated with a Hanovia-450 W medium-pressure lamp equipped with a Pyrex filter. The red solution bleaches in the course of the reaction which takes
$10-12 \mathrm{~h}$. The $\mathrm{N}_{2}$ stream was maintained till the process came to an end. The reaction mixture was treated with aqueous $\mathrm{NaHCO}_{3}$, dried $\left(\mathrm{MgSO}_{4}\right)$ and evaporated. The crude product was purified by a twofold column chromatography ( $3 \times 50 \mathrm{~cm} \mathrm{SiO} 2$, petroleum ether, b. p. $40-70^{\circ} \mathrm{C} / \mathrm{CH}_{2} \mathrm{Cl}_{2}$ $5: 1$ to $2: 1$ ).
